Ricin is a potent protein cytotoxin. Ricin is derived from the beans of the castor plant (*Ricinus communis*) (Figure 58-4). Castor beans are widely available throughout the world. The toxin also is relatively easy to extract. Ricin can be made into a mist, powder, or pellet. When ricin is inhaled as an aerosol, it results in pulmonary toxicity with severe respiratory symptoms within 8 hours. This is followed by acute hypoxic respiratory failure in 36 to 72 hours.[12] (Nonspecific findings of weakness, fever, vomiting, cough, hypoxemia, hypothermia, and hypotension in large numbers of patients might suggest exposure to several respiratory pathogens.) If ricin is ingested, severe gastrointestinal symptoms occur with rapid onset of nausea, vomiting, abdominal cramps, and severe diarrhea. This is followed by vascular collapse and death.

TREATMENT

No antidote exists for ricin poisoning. Treatment is aimed at avoiding exposure and eliminating the toxin from the body as quickly as possible. Patients who have inhaled ricin should be moved to an area with fresh air, clothing contaminated with the toxin should be removed, and the patient should be decontaminated (see Chapter 57). The prehospital care may include airway, ventilatory, and circulatory support. Seizures, hypotension, and respiratory failure should be anticipated.

Smallpox

Smallpox was declared extinct by the World Health Organization in 1980 because of near-universal vaccination. However, the virus could be used as a biological weapon. The variola virus that causes smallpox is fairly stable. The infectious dose also is small. Moreover, an aerosol release of the virus would be widely spread. The incubation period for smallpox is about 12 days following exposure. The virus usually is spread by an infected person releasing infected saliva from the mouth into the air. Persons in close or prolonged contact to the infected person inhale the virus. Smallpox also can be spread through direct contact with infected body fluids or contaminated objects such as bedding or clothing. Signs and symptoms of the disease include high fever, fatigue, headache, and backache. These are followed within 2 to 3 days with the smallpox rash and skin lesions. These lesions finally form crusts. Upon healing, the lesions leave depressed, depigmented scars (Figure 58-5). Permanent joint deformities and blindness may

FIGURE 58-5 Smallpox lesions.

follow recovery. The death rate from smallpox is about 30% in unvaccinated persons.[13]

Vaccine immunity may prevent or modify the illness. At this time, however, the federal government does not recommend prophylactic vaccination for health care workers or the general public because of the possibility of toxic or allergic reactions.[14] If an attack is known or imminent, smallpox response teams whose members have received the vaccine will administer the vaccine to others. They also will care for victims who have been exposed. Currently, the United States has enough smallpox vaccine in storage to vaccinate everyone in the country who might need it in the event of an emergency.[15] Production of a new vaccine is also under way.

TREATMENT

There is no proven treatment for smallpox. However, several antiviral drugs are being studied. Patients with smallpox should receive supportive care provided by vaccinated personnel. The personnel must use universal precautions. (This includes appropriate respiratory protection.) Objects that come in contact with the patient require disinfection. (Examples of such objects are bed linens, clothing, ambulances, and equipment.) This disinfection must be by fire, steam, or sodium hypochlorite solution.

CRITICAL THINKING

Your employer asks you to get the smallpox vaccination. Where can you look to find information about the side effects and risks of immunization with this vaccine?

Tularemia

Tularemia is a serious illness caused by the bacterium *Francisella tularensis.* This bacterium is found in animals (especially rodents, rabbits, and hares). (The illness can be caused by skinning the fresh carcass of rabbits ["rabbit fever"], if the bacterium is introduced through broken skin. Rubber gloves should be worn when handling animals that might harbor the bacterium.) The disease is highly infectious. Some strains are resistant to antibiotics. The bacterium responsible for tularemia can be delivered in a bioterrorism attack by aerosol. Infection may result from inhalation of the aerosol. It also may result from the skin, mucous membranes, respiratory tract, or gastrointestinal tract (via contaminated soil, water, food, or animals) being exposed to the virus. Transmission of the disease from person to person does not occur. The development of signs and symptoms varies widely (from 1 day to 2 weeks). This is based on the strength of the strain and the route of exposure. Following a bioterrorism attack with the agent, patients may complain of an abrupt onset of an acute febrile illness (headache, chills, general malaise). They also may complain of gastrointestinal illness that includes nausea, vomiting, and diarrhea. If left untreated, septic tularemia may lead to disseminated intravascular coagulation with bleeding, acute respiratory failure, and death.

TREATMENT

The disease is managed with antibiotics. The patient may require airway, ventilatory, and circulatory support. Although funding has been provided for the development of a vaccine for civilian use, one is not currently available in the United States. The U.S. Department of Defense has developed an experimental tularemia vaccine. To date, health officials have limited the use of this vaccine to laboratory and other high-risk workers.[16]

Viral Hemorrhagic Fevers

Viral hemorrhagic fevers (VHFs) refer to a group of illnesses caused by several distinct families of viruses that include arenaviruses, filoviruses, bunyaviruses, and flaviviruses. The VHFs have limited geographical ranges and are found mostly across eastern and southern Africa, South America, and the Pacific islands.[17] Most are highly infectious if spread as an aerosol. These viruses naturally reside in animals (e.g., cotton rat and deer mouse) or arthropods (e.g., ticks and mosquitoes). The viruses are fully dependent on these living hosts for reproduction and survival. Viruses that cause hemorrhagic fever usually are transmitted to human beings during contact with urine, fecal matter, saliva, or other body excretions from an infected rodent or by a bite from an infected mosquito or tick. Some VHFs (e.g., **Ebola** and **Marburg**) also can spread from person to person following an initial infection. This type of infection most often results from close contact with infected persons through their body tissues and fluids.

Viral hemorrhagic fevers cause a multisystem syndrome. The syndrome is characterized by hemorrhage and life-threatening disease. Signs and symptoms vary by the type of VHF. However, they often include fever, fatigue, dizziness, muscle aches, loss of strength, and exhaustion. Patients with severe cases of VHF may bleed from mucous membranes, from internal organs, or from the mouth, eyes, or ears. (Death rarely results from this blood loss.) Shock, renal failure, central nervous system dysfunction, coma, and seizures may develop with severe infection. These may lead to a fatal outcome.

TREATMENT

Therapy for patients with VHFs is supportive. With the exception of *yellow fever* and *Argentine hemorrhagic fever,* for which vaccines have been developed, no vaccines exist that can protect against these diseases. The goals of therapy are to maintain vital functions. This may allow for recovery in some patients.

NUCLEAR AND RADIOLOGICAL THREATS

Nuclear explosions can cause deadly effects from blinding light, intense heat (thermal radiation), initial nuclear radiation, blast, fires started by the heat pulse, and secondary fires caused by destruction. A **radiological dispersion device** (RDD) is also called a "dirty nuke" or "dirty bomb." The use of such a device as a terrorist weapon is considered far more likely than use of a true nuclear device. (A true nuclear device uses weapons-grade uranium or plutonium.)[18] These dirty bombs appeal to terrorists. They require little technical knowledge to build and deploy compared with that of a true nuclear device. These radioactive materials also are used widely in medicine, agriculture, industry, and research. They are readily available and easy to obtain.

NOTE

Radiological attacks are a credible threat. However, they would not result in the hundreds of thousands of deaths that could be caused by a crude nuclear weapon that requires a fission reaction. A radiological attack, however, could cause serious illness in persons in the immediate area, contaminate several city blocks, and require costly cleanup (if even possible).

The main type of RDD combines an explosive, such as dynamite, with a radioactive material. The extent of contamination would depend on a number of factors. These include the size of the explosive, the amount and type of radioactive material used, and weather conditions (e.g., wind). The detonation of an RDD releases radioactive fallout. This could cause radiation sickness, severe burns, and long-term cancer fatalities. In most cases the conventional explosive itself would result in more deaths than from exposure to the radioactive material.[19] A second type of RDD might involve a powerful radioactive source hidden in a public place. It may be hidden, for example, in a trash can in a busy train or subway station. In such a place, persons passing close to the source might receive a significant dose of radiation.

CRITICAL THINKING

What emergency medical services groups or divisions should you consider setting up if there is a report of a dirty bomb explosion?

Emergency Care

As described in Chapter 39, the principles of *time, distance,* and *shielding* should be used for personal protection and for the protection of others:

1. Limit the amount of *time* at a radiological scene. Fallout radiation loses its intensity fairly rapidly. Use or wear radiation detection monitors.
2. Increase the *distance* between you and the scene.
3. *Shield* yourself with appropriate personal protective equipment (PPE), geography, or structural materials whenever possible. Your protection increases in proportion to the number of heavy, dense materials located between you and the fallout particles.

After dealing with the initial blast, the top priorities are the treatment of radiation sickness, the containment and monitoring of radioactive fallout, evacuation, and decontamination.

LOOK AGAIN
See Chapter 39: Burns, pp. 1142-1144.

INCENDIARY THREATS

Incendiary devices are firebombs. These devices range from a simple Molotov cocktail (a bottle containing a rag soaked in gasoline that is ignited) to much larger and sophisticated devices. Their main use in terrorism is to generate panic (a *weapon of mass disruption*). However, they are also capable of causing loss of life and property damage from fire. Depending on the severity of the attack, primary concerns may include the following:

- The possibility for large numbers of injured victims and fatalities
- Significant damage to buildings and the infrastructure of a community
- Overwhelming of local resources (emergency response agencies, hospitals, mental health agencies)
- The involvement of law enforcement at local, state, and federal levels because of the criminal nature of the event
- The closing of workplaces and schools
- Possible restrictions on domestic and international travel
- The need for evacuation and extended cleanup
- Public fear that can continue for a prolonged period

Emergency Care

Emergency care depends on the nature of the attack. Care may include providing initial wound care for injured victims at a small-scale event. However, care also may include managing a scene with multiple patients at a large-scale event (see Chapter 54). As with any emergency response, EMS crews should not approach the scene until it has been made safe by the proper personnel. Following the initial explosion, detonation of a second device is possible. The second device may be designed to injure or kill emergency response personnel or bystanders. In addition,

BOX 58-4 Required Resource Guidelines and Recommendations for EMS Response to Terrorist Bombing Attacks[20]

- Personnel must:
  1. Be appropriately trained, equipped, and knowledgeable about chemical, biological, radiological, nuclear, and explosives (CBRNE) detection, personal protection, and decontamination.
  2. Be educated in the care of blast-related injuries for adult and pediatric patients.
  3. Be prepared to institute triage.
  4. Have the necessary resources and be capable of rapidly detecting CBRNE agents to assist with the decontamination plan.
  5. Be prepared to institute and participate in a unified incident command.
- An incident management process to address 72-hour operations.
- A communications system that is interoperable with the public safety disciplines (fire, law enforcement, EMS, and emergency management) and with receiving hospitals, other health care facilities, and local public health officials.
- Rapid access to a medical cache(s) sufficient to treat the volume of critically injured patients.
- Ambulance resources to transport critically injured patients.
- Alternative resources (e.g., buses) to transport noncritically injured persons.
- Decontamination equipment for ambulatory and nonambulatory patients. Equipment should be rapidly deployable to the explosion site, a secondary treatment site, or a hospital.
- Secondary triage and treatment sites that can be determined and implemented within the community.
- A demobilization plan that includes access to mental health professionals.

biological, chemical, or nuclear materials may have been used in the explosion. Thus it is critical to personal safety not to enter the scene until the area is determined to be safe. The CDC has issued required resource guidelines and recommendations for EMS response to terrorist bombing attacks (Box 58-4).

SPECIFIC CHEMICAL THREATS

Specific chemicals that may be used in war and acts of terrorism include nerve agents, poisonous gases, and blister agents. The deliberate release of these chemicals in the form of toxic gas, liquid, or solid can poison persons or the environment.

Nerve Agents

Nerve agents were used in military conflicts in the Persian Gulf in the 1980s. They also were used in terrorist attacks in Japan in 1995. They are the most toxic and rapidly acting of the known chemical warfare agents.[21] Nerve agents are similar to organophosphates in terms of their mechanism of action and the kinds of harmful effects they cause. (However, they are more potent [see Chapter 34].) Nerve agents inhibit the effects of acetylcholinesterase, which causes a cholinergic "overdrive" (*cholinergic crisis*). This disrupts the nerve transmissions in the central and peripheral nervous systems. The extent of poisoning caused by nerve agents depends on the amount, route, and length of exposure. Mildly or moderately exposed persons usually recover fully. Severely exposed persons are not likely to survive. The nerve agents discussed in this chapter are sarin (BG), soman (GD), tabun (GA), and VX.

NOTE

Allied forces in World War II coined these nerve agents as "G" series. They were so named because they were first developed by German scientists during the war.[22]

CRITICAL THINKING

Would you expect a fast or slow heart rate if the patient has been exposed to a nerve agent?

Sarin (also known as "BG") is a clear, colorless, and tasteless liquid that has no odor in its pure form. However, sarin can evaporate into a vapor (gas) and spread into the environment. The agent also mixes easily with water. This allows for contamination by persons touching or drinking water. Symptoms may begin within minutes to hours after exposure. They may include headache, salivation, chest pain, abdominal cramps, wheezing, fasciculations (i.e., muscle twitching), seizure, and respiratory failure that possibly can lead to death.

Soman (also known as "GD") is a clear, colorless, tasteless liquid with a slight camphor odor. The odor is similar to the smell of Vicks VapoRub or a rotting fruit odor. The agent can vaporize if heated. Compared with other nerve agents, soman is more volatile than VX but less volatile than sarin. (The higher the volatility of a chemical, the more likely it will evaporate and disperse into the environment.) Persons can be exposed to the vapor even if they do not come in contact with the liquid form. Symptoms may begin within seconds to hours after exposure. They include headache, salivation, chest pain, abdominal cramps, wheezing, fasciculations, seizure, and respiratory failure that possibly can lead to death.

Tabun (also known as "GA") is a clear, colorless, tasteless liquid with a faint fruity odor. The chemical can vaporize if heated. Thus persons can be exposed to the nerve agent by skin or eye contact or by inhalation. The agent also mixes easily with water. This allows for possible cutaneous exposure and exposure to the

gastrointestinal tract if contaminated food or water is ingested. Moreover, secondary contamination is possible. This would occur from clothing or personal articles that have been contaminated by tabun vapor. Symptoms generally appear within a few seconds after exposure to tabun vapor and within 18 hours after exposure to liquid tabun.[21] Signs and symptoms of mild to moderate exposure to tabun include watery eyes, blurred vision, headache, weakness, cough, drooling, polyuria, excessive sweating, fasciculations, hypotension or hypertension, and cardiac abnormalities. With severe exposure, patients may experience loss of consciousness, seizures, and cardiorespiratory arrest. Severely poisoned patients are not likely to survive.

VX

VX (*O*-ethyl *S*-[2-(diisopropylamino)ethyl]methylphosphonothioate) is a thick, amber-colored, odorless liquid. It resembles motor oil and is the most potent of all nerve agents. VX is considered to be much more toxic when absorbed through the skin and somewhat more toxic by inhalation than are other nerve agents. VX is primarily a liquid exposure hazard. However, if heated to very high temperatures, it can turn into small amounts of vapor. Following release of VX into the air, persons can be exposed through skin contact, eye contact, or inhalation. VX also can be released into the water. This allows for exposure by ingestion or absorption. Symptoms will appear within a few seconds after exposure to the vapor form of VX. They will appear within a few minutes to up to 18 hours after exposure to the liquid form. Signs and symptoms of exposure are the same as those for other nerve agents.

TREATMENT

Treatment for exposure to nerve agents consists of quickly removing the agent from the body and supporting the patient's vital functions. If vapor exposure has occurred, the patient should be moved quickly to an area of fresh air. If the exposure occurred in an open-air environment, the patient should be moved uphill and upwind from the contamination site. Many nerve agents are heavier than air and will settle in low-lying areas. The patient's clothing should be removed and the patient should be decontaminated by trained personnel. A person's clothing and other contaminated surfaces can release nerve agents for about 30 minutes after exposure.[23] Thus secondary contamination is possible.

Atropine and ***pralidoxime chloride*** are antidotes (available in autoinjector kits, e.g., MARK I and DuoDote kits) for nerve agent toxicity (Table 58-1). They work by blocking the effects of acetylcholine (see Chapter 34 and the Emergency Drug Index). Large doses of these drugs and repeated administration may be required. ***Diazepam*** or ***lorazepam*** may be indicated if seizures are present. (The paramedic should consult with medical direction before administering these drugs if muscle twitching is present.) Once seizures begin, they can be almost impossible to stop. Caring for patients who have ingested a nerve agent should be guided by medical direction, a poison control center, or other authority.

TABLE 58-1 Recommendations for Prehospital Nerve Agent Therapy

	Antidotes*		
Patient's Age	**Mild/Moderate Symptoms†**	**Severe Symptoms‡**	**Other Treatment**
Infant (birth to 2 yr)	Atropine: 0.05 mg/kg IM; 2-PAM-Cl: 15 mg/kg IM	Atropine: 0.1 mg/kg IM; 2-PAM-Cl: 25 mg/kg IM	For severe exposures, assisted ventilation should be started after administration of antidotes.
Child (2-10 yr)	Atropine: 1 mg IM; 2-PAM-Cl: 15 mg/kg IM	Atropine: 2 mg IM; 2-PAM-Cl: 25 mg/kg IM	
Adolescent (>10 yr)	Atropine: 2 mg IM; 2-PAM-Cl: 15 mg/kg IM	Atropine: 4 mg IM; 2-PAM-Cl: 25 mg/kg IM	**Repeat atropine (2 mg IM)** at 5- to 10-min intervals until secretions have diminished and breathing is comfortable or airway resistance has returned to near normal.
Adult	Atropine: 2-4 mg IM; 2-PAM-Cl: 600 mg IM *Or* 1 MARK I kit IM	Atropine: 6 mg IM; 2-PAM-Cl: 1800 mg IM *Or* 3 MARK I kits IM	
Elderly, frail	Atropine: 1 mg IM; 2-PAM-Cl: 10 mg/kg IM	Atropine: 2-4 mg IM; 2-PAM-Cl: 25 mg/kg IM	

Modified from Agency for Toxic Substances and Disease Registry: *Medical management guidelines (MMGs) for nerve agents,* www.atsdr.cdc.gov.
*2-PAM-Cl (2-pralidoxime chloride) solution must be prepared from an ampule containing 1 g of desiccated 2-PAM-Cl: inject 3 mL of saline and 5% distilled or sterile water into the ampule and shake well. The resulting solution is 3.3 mL of 300 mg/mL 2-PAM-Cl.
†Mild to moderate symptoms include localized sweating, muscle fasciculations, nausea, vomiting, weakness, and dyspnea.
‡Severe symptoms include unconsciousness, convulsions, apnea, and flaccid paralysis.

Poisonous Gases

Poisonous gases were popular weapons in World War I. Although they have not been used as toxic pulmonary inhalants by the military since 1918,[21] they are produced in large quantities worldwide for use in the industrial sector. They are widely available. Thus use of these gases for acts of terrorism is a possibility. The gases described in this section are chlorine and phosgene.

Chlorine is a yellow-green gas with an odor that has been described as a mixture of pineapple and pepper. Chlorine gas can be pressurized and condensed to change it into a liquid. In liquid form, chlorine can be shipped and stored. When liquid chlorine is released, it quickly vaporizes into a gas that stays close to the ground and spreads rapidly. If chlorine is released into the air, persons may be exposed to chlorine gas through skin or eye contact or by inhalation. If chlorine liquid is released into water, exposure can occur by touching or drinking contaminated water or by ingesting food that was prepared with the contaminated water. Like other chemical agents, the extent of poisoning depends on the amount, route, and duration of exposure to the agent. Signs and symptoms may include cough; chest pain; burning sensation in the nose, eyes, or throat; watery eyes; blurred vision; gastrointestinal disturbances; dermal burns from skin contact; and shortness of breath and dyspnea. Pulmonary edema can develop within 2 to 4 hours following inhalation of the gas.[24]

Phosgene (also known as "CG") is a poisonous gas that appears as a grayish white cloud and smells of newly mowed hay. With cooling and pressure, the gas can be condensed into a liquid so that it can be shipped and stored. When liquid phosgene is released, it quickly vaporizes into a gas that stays close to the ground and spreads rapidly. Inhaled phosgene damages the lungs, producing a burning sensation, cough, and labored breathing. Pulmonary edema with frothy sputum production may develop. Cutaneous exposure to the gas can result in skin or eye injury. Exposure also can occur by touching or drinking water contaminated with the gas or by ingesting food that was prepared with the contaminated water. In addition to the signs and symptoms noted previously for chlorine exposure, phosgene poisoning may cause hypotension and heart failure. In lethal doses, death can occur within 48 hours.[25]

TREATMENT

No antidotes exist for chlorine or phosgene poisoning. Treatment for exposure to these gases consists of removing them from the body as soon as possible and providing supportive medical care. All patients should be moved to an area of fresh air and to the highest ground possible (if exposure occurred in an open air space). The patient's clothing should be removed. Then the patient should be decontaminated by trained personnel.

Blister Agents

Blister agents or **vesicants** are chemicals with highly irritating properties that produce fluid-filled pockets on the skin and damage to the eyes, lungs, and other mucous membranes. In addition to cutaneous effects from exposure to these agents, blister agents also can cause loss of vision, convulsions, and respiratory failure. The gastrointestinal system, central nervous system, and bone marrow also can be affected through systemic absorption. Symptoms of exposure may be delayed until hours after exposure. The major chemicals in this category are sulfur mustard (H, HD, HT), nitrogen mustard (HN-1, HN-2, HN-3), and lewisite (L, L-1, L-2, L-3). Phosgene oxime is more of an urticant, producing irritation without blisters. However, the gas still is classified as a vesicant.

Mustard (*sulfur mustard* and *nitrogen mustard*) is an oily liquid that comes in a variety of colors ranging from brown to yellow. It may smell like garlic, onion, horseradish, or mustard itself. *Lewisite* is an oily, odorless liquid. Lewisite is more volatile than mustard and smells like geraniums in its gaseous state. (Unlike mustard, in which symptoms may be delayed, lewisite causes immediate pain and irritation on contact.) *Phosgene oxime* is a colorless solid or yellowish brown liquid. It may have a peppery or pungent odor. Like lewisite, this agent causes immediate pain and irritation on contact with the skin or mucous membranes.

TREATMENT

After ensuring personal safety (including the use of appropriate personal protective equipment), the initial assessment and treatment of the patient should begin with airway, ventilatory, and circulatory support as needed. Immediate decontamination may reduce damage to tissue. All skin exposures should be treated with standard burn care. Advanced cardiac life support protocols should be followed for any patient with cardiac or respiratory problems. Advanced trauma life support protocols should be followed for any trauma patient. The signs and symptoms may not develop for several hours following exposure to some blister agents. Thus a patient with a significant exposure should be evaluated by a physician. Patients who have only mild symptoms should be advised to seek physician evaluation if signs and symptoms worsen.

EXPLOSIVE THREATS

An **explosive** is a bomb. Bombs can be made from a variety of dangerous materials and can be made in a variety of sizes weighing several ounces to several thousand pounds. Explosives used by terrorists are often classified by the following categories[26]:

- *Unconventional use:* A conventional object used in an unconventional way to create mass destruction. In the September 11, 2001, attacks on the World Trade Center and the Pentagon, hijackers flew passenger planes into their intended targets, relying on the impact of the planes and their full fuel tanks to create havoc.

- *Vehicle bomb:* Usually large powerful devices that consist of a large quantity of explosives fitted with a timer or a remotely triggered detonator packed onto a car or truck.
- *Pipe bomb:* A quantity of explosives sealed into a length of metal or plastic pipe. A timing fuse usually controls detonation, but other methods can be used, including electronic timers, remote triggers, and motion sensors. These are the most common explosive devices and are at the opposite end of the scale from vehicle bombs in terms of size and power.
- *Satchel charge:* An old military term for an explosive device in a canvas-carrying bag. In recent history, "daypacks" or knapsacks have been used for the carrying device, and the explosives have contained antipersonnel materials such as nails and glass to inflict more casualties.
- *Package or letter bomb:* Explosive material contained in a package or letter that usually is triggered by opening of the package (Figure 58-6).

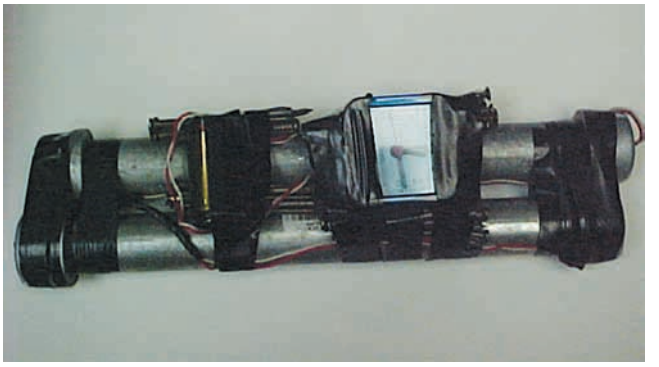

FIGURE 58-6 Pipe bomb.

NOTE

An **improvised explosive device** (IED) is also known as a *roadside bomb*. These devices are "homemade" bombs constructed of explosives attached to a detonator. IEDs are used in terrorist actions or in unconventional warfare. In 2007 they had become responsible for nearly two thirds of the American combat deaths in Iraq.[27]

SHOW ME THE EVIDENCE

The authors reviewed 35 research articles related to terrorist bombing incidents that involved 30 or more patients or that caused structural collapse of 1 or more floors. The 29 terrorist bombing incidents identified resulted in 8362 injured patients, and 903 died immediately. Deaths were highest (25%) in structural collapse bombings, followed by confined-space (8%) and open-air (4%) bombings. Most deaths occurred immediately with fewer deaths occurring in the ED or during hospital admission. Patients injured in structural collapse bombings had a higher incidence of fractures. Confined-space bombings produced a higher incidence of pressure-related injuries affecting the lungs and tympanic membranes, burns, and injuries to the spleen or liver. Soft tissue injury was more prevalent in open-air bombing patients. Although all injury types are found in all bombing locations, health care personnel should anticipate a higher incidence of specific injury based on the location of the bombing.

From Arnold JL, Hallpern P, Tsai M-C, et al: Mass casualty terrorist bombings: a comparison of outcomes by bombing type, *Ann Emerg Med* 43(2):263-273, 2004.

Emergency Care

Like the incendiary devices described earlier, the care for victims of an explosion may vary. Treatment may require only minor wound care to several persons. Or treatment could be a large-scale event. The larger events may have many patients and casualties. The incident may involve secondary explosions and chemical and biological threats. Thus it is critical to personal safety not to enter the scene until the area is determined to be safe by the proper personnel. As described Chapter 37, there are many injuries that result from explosive forces, including *primary, secondary, tertiary, and quaternary blast injuries*.

LOOK AGAIN

See Chapter 37: Trauma Overview and Mechanism of Injury, pp. 1090-1092.

DEPARTMENT OF HOMELAND SECURITY

Following the terrorist attacks on the World Trade Center in New York City on September 11, 2001, the Department of Homeland Security was established through the Homeland Security Act of 2002 (H.R. 5005).[28] The three primary missions of the Department of Homeland Security are to (1) prevent terrorist attacks within the United States, (2) reduce America's vulnerability to terrorism, and (3) minimize the damage from potential attacks and natural disasters. To help meet these goals, a uniform national threat advisory system (NTAS) (Homeland Security Advisory System) was developed to inform federal agencies, state and local officials, and the private sector of terrorist threats and appropriate protective actions.

The Homeland Security Advisory System establishes two threat alerts that are issued when credible information is available. These alerts will include a clear statement that there is an **imminent threat** or **elevated threat**. Using available information, the alerts will provide a concise summary of the potential threat, information about actions being taken to ensure public safety, and recommended steps that individuals, communities, businesses and governments can take to help prevent, mitigate, or respond to the threat. The NTAS Alerts will be based on the nature of the threat: in some cases, alerts will be sent directly to law enforcement or affected areas of the private sector, while in others, alerts will be issued more broadly to the American people through both official and media channels.[29] NTAS

BOX 58-5 Homeland Security Alerts

Imminent Threat Alert: Warns of a credible, specific, and impending terrorist threat against the United States.

Elevated Threat Alert: Warns of a credible terrorist threat against the United States.

Sunset Provision: An individual threat alert is issued for a specific time period and then automatically expires. It may be extended if new information becomes available or the threat evolves.

Alerts contain a **sunset provision** indicating a specific date when the alert expires—there will not be a constant NTAS Alert or blanket warning that there is an overarching threat. If threat information changes for an alert, the Secretary of Homeland Security may announce an updated NTAS Alert. All changes, including the announcement that cancels an NTAS Alert, will be distributed the same way as the original alert (Box 58-5).

GENERAL GUIDELINES FOR EMERGENCY RESPONSE

General guidelines for responding to a scene that may involve hazardous materials were described in Chapter 57. Many aspects of a WMD incident are comparable to other medical, trauma, and hazardous materials incidents. However, there are some significant differences. (1) Terrorists have been known to time secondary events (e.g., booby traps, additional bombs, and armed resistance) to injure emergency responders. (2) A terrorist act is a criminal event. This means that the site becomes a crime scene. Thus everything is considered evidence of the crime. Fear and panic can be expected from the public, patients, and emergency responders. This makes scene safety, security, and crowd control major issues with which to contend. (3) Contingency plans for emergency responders at the scene and at destination facilities will need to be in place. These plans will help emergency responders to deal with the large numbers of upset, agitated, frightened, and injured patients. Large-scale events will likely involve local, state, and federal agency involvement.

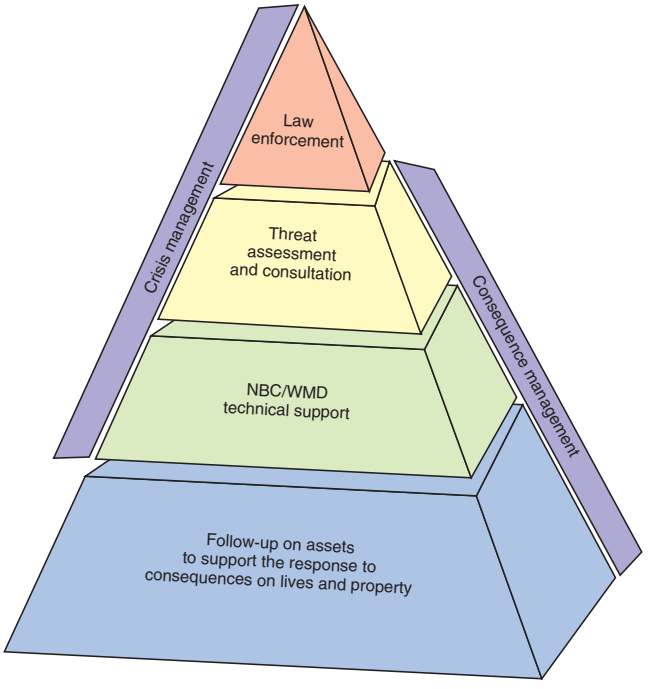

FIGURE 58-7 Relationship between crisis and consequence management.

CRITICAL THINKING

Why will correct, prompt information to the media be critical during a weapons of mass destruction event?

DID YOU KNOW?

The Federal Response Plan and Terrorism Incident Annex

In June 1995, the White House issued Presidential Decision Directive 39 (PDD-39), "United States Policy on Counterterrorism." PDD-39 directed a number of measures to reduce the nation's vulnerability to terrorism, to deter and respond to terrorist acts, and to strengthen capabilities to prevent and manage the consequences of terrorist use of nuclear, biological, and chemical (NBC) weapons including weapons of mass destruction (WMD). PDD-39 discusses crisis management and consequence management.

Crisis management includes measures to identify, acquire, and plan the use of resources needed to anticipate, prevent, and/or resolve a threat or act of terrorism. The laws of the United States assign primary authority to the federal government to prevent and respond to acts of terrorism; state and local governments provide assistance as required. Crisis management is predominantly a law enforcement response. Based on the situation, a federal crisis management response may be supported by technical operations, and by federal consequence management, which may operate concurrently (Figure 58-7).

Consequence management includes measures to protect public health and safety, restore essential government services, and provide emergency relief to governments, businesses, and individuals affected by the consequences of terrorism. The laws of the United States assign primary authority to the states to respond to the consequences of terrorism; the federal government provides assistance as required.

Emergency Responder Guidelines

Emergency responder guidelines have been established by the Office of Justice Program, Office for Domestic Preparedness, to prepare for and respond to incidents of domestic terrorism. These incidents may involve chemical and biological agents and nuclear, radioactive, and explosive devices. Recommended guidelines for EMS providers are as follows[30]:

- Recognize hazardous materials incidents.
- Know the protocols used to detect the potential presence of WMD agents or materials.

- Know and follow self-protection measures for WMD events and hazardous materials events.
- Know procedures for protecting a potential crime scene.
- Know and follow agency/organization scene security and control procedures for WMD and hazardous material events.
- Possess and know how to use equipment properly to contact dispatchers or higher authorities to report information collected at the scene and to request additional assistance or emergency response personnel. Know how to characterize a WMD event and be able to identify available response assets within the affected jurisdiction(s).

Finally, EMS agencies must be prepared to implement incident operations, provide personal and public safety measures, perform appropriate decontamination, and provide emergency medical care specific to the incident.

SUMMARY

- There are five categories of weapons of mass destruction. These include biological, nuclear, incendiary, chemical, and explosive.
- Biological agents include anthrax, botulism, plague, ricin, tularemia, and smallpox.
- Person-to-person spread is possible in patients who are infected with plague or smallpox.
- Nerve agents include sarin, soman, tabun, and VX. Exposure causes a cholinergic overdrive. The antidotes for nerve agent exposure are atropine and pralidoxime chloride.
- Poisonous gases such as chlorine and phosgene cause severe respiratory problems. They also can cause skin and eye injury. Move exposed patients to safety, remove their clothing, and treat their symptoms.
- Dirty bombs could cause heat damage and radiation sickness, severe burns, and cancer.
- The Department of Homeland Security has identified five terrorist threat levels. Each level has specific community-wide emergency preparedness activities to be taken.
- Emergency responders at a WMD incident should recognize hazmat incidents, know protocols to detect WMD, use PPE, know crime-scene procedures, know how to activate more resources, and implement incident operations.

Personal Protective Equipment for Chemical, Biological, Radiological, and Nuclear Agents

INTRODUCTION

Recent terrorist events in the United States underscore the importance of emergency response procedures for dealing with terrorist-related events involving chemical, biological, radiological, or nuclear (CBRN) agents. OSHA and NIOSH continue to work with other federal response agencies to provide accurate, current information to help prepare these on-scene responders.

PERSONAL PROTECTIVE EQUIPMENT (PPE) FOR CBRN RESPONSE

Emergency responses to hazardous substance releases including CBRNs are guided under OSHA's Hazardous Waste Operations and Emergency Response (HAZWOPER) Standard (29 CFR 1910.120[q]). Personal protective equipment is selected to meet the requirements of this standard and Subpart I. NIOSH has developed a respiratory protection approval specifically for CBRN exposures and the Department of Homeland Security also adopted guidelines for appropriate PPE. To use this guidance effectively, an employer must assess the risk of a hazardous substance release to the emergency responders and base the PPE selection on the level of knowledge relative to that risk. This kind of assessment is a typical safety and health evaluation with the unusual caveats that many of the agents are highly toxic by both skin contact and inhalation; typical indicators of exposure such as odor, smoke, or fumes may not be present; exposure monitoring is difficult for some of the compounds; and there may be a locally limited supply of CBRN-approved respirators for a large response during initial emergency operations. Based on the hazardous substances and conditions known to be present, the incident commander in charge of a response shall implement appropriate emergency operations, including selection of appropriate PPE for employees who respond. This includes, at a minimum, PPE meeting the criteria in 29 CFR 1910.156(e) for firefighting operations beyond the incipient stage, 29 CFR 1910.120(q)(3)(iii).

SITE CONTROL

Site control is an important part of managing any emergency response operation. Some guidance for zoning exists in 29 CFR 1910.120 Appendix C and in the NFPA 471 Standard (2002) (Hot, Warm, Cold) with hot denoting a contaminated area where adverse effects might be seen, warm being an initially clean area for close support and decontamination, and cold representing an area with no potential exposure. Other guidance from the DOT Emergency Response Guidebook (2004) provides for an "Initial Isolation Zone" where dangerous or life-threatening concentrations of a substance may exist or a "Protective Action Zone" where serious or irreversible health effects may be seen. The OSHA zones of Red, Yellow, and Green described below are available to be used by incident commanders as complementary guidance for personal protective equipment selection based on the level of knowledge about the WMD events. The use of the Red, Yellow, and Green zones is neither mandatory nor exclusionary of other site control concepts. It is intended to offer flexibility to an incident commander managing a large WMD event within the limitations of current first responder monitoring capabilities.

Red Zone. Areas where significant contamination with chemical, biological, radiological, or nuclear (CBRN) agents has been confirmed or is strongly suspected but area has not been characterized. The area is presumed to be life threatening from both skin contact and inhalation.

Level A protection is generally needed when the active release is still occurring, or the release has stopped but there is no information about the duration of the release or the airborne concentrations of CBRN agents. Respirators chosen initially for responders entering a known release area where CBRNs are suspected should be a positive-pressure self-contained breathing apparatus (SCBA) with a fully encapsulating protective suit until monitoring results allow for other decisions. Level A protection should be consistent with the description in HAZWOPER Appendix B and suits should be appropriate for CBRN agents—that is, they should meet the requirements of NFPA 1994-2001, have been tested by a third party such as the U.S. Army and Soldier and Biological Chemical

Command (SBCCOM), or have undergone other manufacturer testing. An NIOSH-certified CBRN SCBA respirator should be used, if available.

Other prudent work practices should include minimizing exposure time to that essential for lifesaving or initial monitoring, avoiding any unnecessary contact with surfaces or potentially contaminated material, and using natural ventilation flows to reduce exposure, mandatory decontamination, and postexit evaluation for signs and symptoms of exposure.

Yellow Zone. Areas where contamination with chemical, biological, radiological, or nuclear (CBRN) agents is possible but active release has ended and initial monitoring exists.

Areas in close proximity to the release area or that are known to be contaminated and certain job activities on the periphery of the event area should be considered for this zone. Risk factors that should be considered include determining the relative risk for job activities from inhalation based on available air monitoring results, skin contact and absorption potential, proximity to the event, and wind directions. Refer to the specific hazard information pages below to select personal protective equipment and limited work durations to reduce exposure to safe levels. Use the other prudent work practices listed for red zone exposures.

Green Zone. Areas where contamination with chemical, biological, radiological, or nuclear (CBRN) agents is unlikely. This zone covers the area beyond the expected significant dispersal range of the initial event and secondary contamination range caused by traffic and emergency responders.

Even in areas that are believed to be hazard-free, there may be a concern or potential for a minimal level of transient or unknown exposures in the aftermath of an event. The following suggestions for prudent work practices may reduce the amount of concern regarding this potential:

- Inform people of location of event and control zones.
- Provide information regarding signs and symptoms of exposure.
- Suggest a means for reporting suspected exposures.
- Suggest attention to general hygiene practices.
- Provide information on voluntary use of personal protective equipment.

Modified from U.S. Department of Labor, Occupational Safety and Health Administration: OSHA/NIOSH interim guidance—August 30, 2004: chemical-biological-radiological-nuclear (CBRN) personal protective equipment selection matrix for emergency responders, www.osha.gov/SLTC/emergencypreparedness/cbrnmatrix/index.html, accessed 2-4-11.

CHAPTER

59 Putting It All Together: Assessment-Based Management

OBJECTIVES

Upon completion of this chapter, the paramedic student will be able to:

1. Discuss how assessment-based management contributes to effective patient and scene assessment.
2. Describe factors that affect assessment and decision making in the prehospital setting.
3. Outline effective techniques for scene and patient assessment and choreography.
4. Identify essential take-in equipment for general and selected patient situations.
5. Outline strategies for patient approach that promote an effective patient encounter.
6. Describe techniques to permit efficient and accurate presentation of the patient.

KEY TERMS

action plan A plan of action based on the patient's condition and the environment.

assessment-based management Comprehensive care that is based on patient assessment, the patient's history, and the physical examination.

contemplative approach An approach to patient care where a history is obtained and a physical examination is performed before providing patient care.

field impression An impression of the patient's condition that the paramedic makes from pattern recognition and gut instinct that results from experience.

labeling A form of assessment bias where a patient is assigned to a group or is stereotyped.

multitasking The ability to ask questions, take notes, and perform tasks while listening to the patient's answers.

pattern recognition The process of comparing gathered information with the paramedic's knowledge base of medical illness and disease.

presenting the patient The effective communication and transfer of patient information in the course of out-of-hospital and hospital care.

resuscitative approach An approach to patient care that recognizes the need for immediate intervention for patients with life-threatening illness or injury.

tunnel vision A narrow outlook; the focus of attention on a particular problem without proper regard for possible consequences or alternative approaches.

As has been stressed throughout this text, assessment is the foundation of patient care. To perform an effective assessment, the paramedic must be able to pull together many elements. These include pathophysiological principles and physical findings to formulate a field impression and implement a treatment plan for patients with common complaints. The paramedic gathers, evaluates, and synthesizes the information; makes appropriate decisions based on the information; and takes appropriate actions required for the patient's care. The purpose of this chapter is to review and emphasize how assessment-based management "puts it all together."

EFFECTIVE ASSESSMENT

Assessment-based management describes comprehensive care that is based on patient assessment. Effective assessment depends on the patient's history and the physical examination. The paramedic's knowledge of disease allows him or her to hold a high degree of suspicion for possible illness. This knowledge also helps the paramedic to focus the history toward the patient's complaint and associated problems. Likewise, the paramedic must focus the physical examination toward body systems associated with the complaint. Some field situations may impair the thoroughness of the examination. For example, unsafe scenes or entrapment may hinder this process. Still, the paramedic must not overlook the importance of the physical examination or perform it hastily.

Pattern Recognition

Once paramedics obtain the patient's history and perform the physical examination, they can compare the information gathered with their knowledge base of medical illness and disease. They must ask whether the history and physical examination match a recognized pattern of illness. This is known as **pattern recognition.** For example, consider a 55-year-old man with chest pain and shortness of breath. This person "matches" a recognized pattern for acute myocardial infarction. However, a 20-year-old woman with similar complaints and no family history of early myocardial events would not match this pattern. Other examples include a 4-year-old child who is in respiratory distress and drooling (matching a pattern for epiglottitis), and an elderly woman with distended neck veins and respiratory congestion who produces a pink, frothy sputum when she coughs. This person matches a pattern for congestive heart failure. Pattern recognition makes it possible for the paramedic to form a field impression and to begin a treatment plan (Box 59-1). Thus the greater the paramedic's knowledge base and quality of assessment, the greater the probability of appropriate decision making and quality patient care.

CRITICAL THINKING
How can pattern recognition lead you down the wrong path?

(Courtesy Ray Kemp, St. Charles, Mo.)

BOX 59-1 Pattern Recognition for Various Patient Presentations

Paramedics are trained in patient assessment and management priorities for patients with the following:

- Acute abdominal pain
- Allergic reactions
- Altered mental status
- Behavioral problems
- Chest pain
- Dyspnea
- Environmental or thermal problem
- Gastrointestinal bleeding
- Hazardous material or toxic exposure
- Medical and traumatic cardiac arrest
- Obstetrical or gynecological problems
- Seizures
- Syncope
- Trauma or multitrauma

Field Impression and Action Plan

The paramedic forms a **field impression** of the patient's condition from pattern recognition and from "gut instinct" that comes from experience (Figure 59-1). After making a field impression, it must be confirmed through the patient history and physical examination. Then, the paramedic can formulate an **action plan.** This plan is based on the patient's condition and the environment. Using the previous example of the two patients with chest pain, the field impression of the 55-year-old patient most likely leads to an action plan that includes electrocardiogram (ECG) monitoring, pulse oximetry, IV therapy, ***aspirin*** administration, pain relief measures, and perhaps drug therapy for dysrhythmias. The 20-year-old patient's action plan most likely includes ECG monitoring to evaluate and manage supraventricular tachycardia, pulse oximetry, and a more thorough assessment to detect a recent respiratory illness to rule out the possibility of pleurisy or pneumonia.

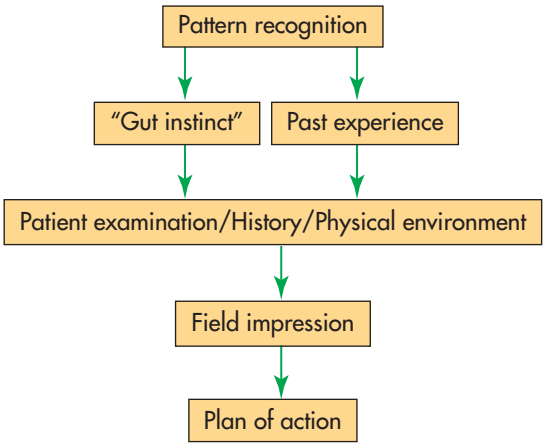

FIGURE 59-1 Matrix pattern.

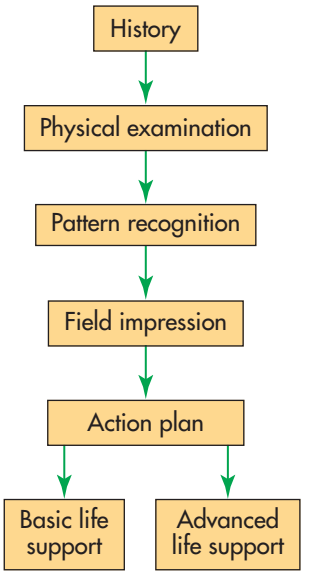

FIGURE 59-2 Effective assessment.

NOTE

The paramedic should not ignore a gut instinct. If something seems wrong, the paramedic should keep looking. Gut instincts often help the paramedic to identify subtle physical findings that are difficult to quantify (e.g., patient affect or dull and lackluster eyes).

Following the field impression and the action plan, the paramedic provides basic and advanced life support treatment (Figure 59-2). These treatments are based on knowledge of the protocols and on judgment—that is, knowing when and how to apply the protocols. Judgment also involves knowing when it is appropriate to deviate from the protocols. For example, consider the administration of ***nitroglycerin*** to a 58-year-old man complaining of ischemic chest pain. His blood pressure measurement is within normal range, but during the patient history he reveals he has taken Viagra within the past 18 hours. As described in Chapter 13, the administration of ***nitroglycerin*** can cause a lethal drop in blood pressure in these patients. Good judgment in this case would lead the paramedic to deviate from a common protocol used to manage normotensive patients with ischemic chest pain.

CRITICAL THINKING

How can you continue to improve your patient care judgment?

Factors That Affect Assessment and Decision Making

Many factors can affect the quality of assessment and decision making by the paramedic. The following factors are discussed in this section:

- Paramedic's attitude
- Patient's willingness to cooperate
- Distracting injuries
- Labeling and tunnel vision
- Environment
- Patient compliance
- Manpower considerations

CRITICAL THINKING

Have you ever seen any of these factors affect patient care?

SHOW ME THE EVIDENCE

These authors examined the elements of cognitive psychology involved in endotracheal intubation. They noted that this process is more complex than it may first appear because it is a psychomotor skill that not only involves skills-based processing but also sometimes requires algorithmic or rules-based processing; it can even encompass knowledge-based processing when unusual or difficult situations are present. They concluded that these findings have significant implications related to patient safety and EMS education.

From Wang HE, Katz S: Cognitive control and prehospital endotracheal intubation, *PEC* 11(2):234-239, 2007.

PARAMEDIC'S ATTITUDE

The paramedic must be professional and nonjudgmental in all actions. These traits are required to perform an effective assessment. A biased or judgmental attitude can "short circuit" the information-gathering process. This in turn can cause the paramedic to overlook important patient data. For example, a paramedic who assumes that an indigent patient is intoxicated may not consider complications from

diabetes or drug use, head injury or hypoxia, or hypovolemia that may have resulted from an internal injury.

PATIENT'S WILLINGNESS TO COOPERATE

Patient cooperation is important in providing patient care. Patients who do not cooperate can complicate the patient assessment required to formulate an action plan. As discussed in earlier chapters, the paramedic should evaluate patients who are uncooperative, restless, or belligerent for the following conditions:

- Alcohol or other drug intoxication
- Head injury or concussion
- Hypoglycemia
- Hypothermia
- Hypovolemia
- Hypoxia
- Psychiatric illness
- Stroke

Distracting Injuries. Obvious but non–life-threatening injuries can distract the paramedic from performing a thorough assessment for more serious problems. Examples include open fractures and facial bleeding that is profuse. If necessary, these wounds should be covered with dressings during the assessment. This will help the paramedic to focus on the more serious problems.

LABELING AND TUNNEL VISION

Labeling and **tunnel vision** can lead to an inaccurate assessment and an incorrect field impression. For example, labeling a patient as "just another drunk" can lead to a biased assessment. Another example is labeling someone who has been transported by ambulance many times for minor complaints or imagined illness as a "frequent flyer." Tunnel vision is assuming an incorrect field impression based on a misplaced or an uneducated gut instinct, or focusing on only a portion of the presenting illness. Either of these assumptions can cause the paramedic to miss the "big picture." Like labeling, tunnel vision can result in a rushed judgment early in the patient assessment and an inappropriate action plan.

ENVIRONMENT

Factors in the environment can adversely affect assessment techniques and decision making at the scene. Examples include scene chaos, violent or dangerous situations, crowds of bystanders or other emergency workers, severe weather, and high noise levels. After ensuring personal safety, the paramedic should quickly establish control of the environment. This can include requesting the help of law enforcement personnel to control the scene so that appropriate assessment and care can be delivered without distraction.

PATIENT COMPLIANCE

The patient's willingness to cooperate and comply with the assessment may depend on his or her trust in the paramedic crew. For example, the patient who perceives the paramedic as competent and professional often provides a thorough history. The patient also often will agree to a complete physical examination. Other factors that can affect compliance are cultural and ethnic barriers. As described in Chapter 17 and Chapter 18, these may include language barriers and religious and social beliefs, among others.

MANPOWER CONSIDERATIONS

Depending on the EMS agency, crews may consist of a single paramedic and an EMT, two paramedics, or several types or groups of responders (e.g., EMS, fire and rescue, and police). In cases in which only EMS is involved and only one paramedic is at the scene, the paramedic will work with the EMT to develop a proper sequence for gathering information and providing care. If two paramedics are available, the information gathering and treatment often can occur simultaneously, with each paramedic assuming specific duties. If multiple responders and agencies are at the scene, roles and duties should be defined in advance. For example, one paramedic may be in charge of history taking and conferring with medical direction. Another paramedic may be in charge of treatment. The fire-rescue members may be in charge of extrication and gathering equipment. Finally, law enforcement personnel may be in charge of securing the scene.

CRITICAL THINKING

How can too many paramedics on the scene have a negative influence on patient assessment and care?

Assessment and Management Choreography

In cases where multiple responders are at the scene of an emergency, a coherent assessment can be difficult. A large emergency response may occur with multiple-tier response systems (e.g., EMS, fire, and police). The situation often is made more complex if the responders are trained at the same level (e.g., paramedic) without a clear direction for individual duties. Therefore members of the response team must have a preplan for deciding roles. The team can assign these predesignated roles by shift or crew, or they can rotate them among team members.

An example of a preplan for two paramedics is to assign one as the *team leader* and one as the *patient care person*. This type of plan must be flexible in rapidly changing field situations. However, the basic "game plan" allows others to participate and is important in preventing confusion at the scene. The following are sample responsibilities for each of the paramedics in this type of preplan:

1. Team leader responsibilities
   a. Accompanies the patient to definitive care
   b. Establishes contact and a dialogue with the patient
   c. Obtains the history
   d. Performs the physical examination

e. Presents the patient and gives verbal reports over the radio or after definitive care
f. Completes all documentation
g. Tries to maintain the overall patient perspective and provides leadership to the team by designating tasks and coordinating transportation
h. Designates and actively participates in critical interventions during the resuscitative phase of the primary survey
i. Acts as initial EMS command in multiple-casualty situations (see Chapter 54)
j. Interprets the electrocardiogram, communicates with medical direction and relays drug orders, controls access to bags, and documents drug administration and effects during advanced cardiac life support

2. Patient care person responsibilities
a. Provides scene cover (watches the team leader's back)
b. Gathers scene information and talks to family members and bystanders
c. Obtains vital signs
d. Performs skills and interventions as requested by the team leader (e.g., attaches monitor leads, provides oxygen, initiates intravenous access, administers drugs, and obtains transportation equipment)
e. Acts as triage group leader in multiple-casualty situations
f. Administers drugs; monitors endotracheal tube placement, pulse oximetry, and basic life support interventions during advanced cardiac life support

THE "RIGHT STUFF"

Having the "right stuff" means carrying the right equipment to the patient's side. Not having the "right stuff" can compromise care and also can cause panic and confusion. The paramedic crew should always be prepared for the worst event. They should carry essential equipment to manage every aspect of patient care, including cardiac monitoring and defibrillation (Box 59-2). The concept of having the "right stuff" can be compared with backpacking. A person who is backpacking must have essential items that are downsized to facilitate rapid movement with minimum weight and bulk.

OPTIONAL "TAKE-IN" EQUIPMENT

In addition to essential equipment for the EMS crew, other equipment can be carried to the patient's side. For example, most EMS systems require that the paramedic carry drug bags and kits for IV supplies. This includes those agencies that have nontransporting emergency vehicles staffed by paramedic personnel as well. Most EMS systems require that paramedics carry these supplies even though they are not appropriate for every patient contact. Other factors that can affect what equipment the paramedic carries to the patient's side depend on the following:

- Local protocol
- Standing order flexibility
- Number of paramedic responders
- Difficulty in accessing patients

Other items that are essential on every call include patient care reports, worksheets, or computer notation devices. Personal items such as pens or pencils, wristwatches, flashlights, and portable radios or cellular phones will also be needed. Personal protective equipment should be readily available on every response.

BOX 59-2 Essential Items for All Aspects of Patient Care

Personal Protection
Eye shields
Gloves
Gowns
Masks

Airway Control
Endotracheal tubes, stylettes, and tape
Laryngoscope and blades
Nasal airways
Oral airways
Rigid Yankauer and flexible suction catheters
Suction (electrical or manual)

Breathing
Large-bore intravenous catheter for thoracic decompression
Manual ventilation bag-valve-mask device
Mouth-powered ventilation device (pocket mask)
Occlusive dressings
Oxygen masks, cannulae, and extension tubing
Pulse oximetry
Oxygen tank and regulator
Spare masks

Circulation
Bandages and tape
Blood pressure cuff and stethoscope
Dressings
Infection-control supplies (gloves and eye shields)
Intravenous fluids, catheters, and tubing
Note pad and pen or pencil or electronic device

Disability and Dysrhythmia
Cardiac monitor and defibrillator
Flashlight
Rigid collar

Exposure
Scissors
Space blanket or other device to cover and protect the patient

CRITICAL THINKING
Have you been on ambulance calls when you did not have the right equipment? How did it affect patient care?

GENERAL APPROACH TO THE PATIENT

A calm and orderly manner is important for the paramedic when approaching a patient. As described in Chapter 1, the paramedic must look and act the part of a professional. This, in addition to a caring and confident bedside manner, will help gain the patient's trust and cooperation. Patients may not be able to rate medical performance; however, they generally are very good at rating "people skills" and service.

As previously described, a preplan should be in effect to prevent confusion at the scene and improve the accuracy of patient assessment. Ideally, one team member should be responsible for talking to the patient. This member should use an active and concerned dialogue that allows for careful listening. Taking notes when acquiring the history demonstrates a thorough assessment to the patient and prevents the paramedic from asking repetitive questions. All essential equipment should be at the patient's side, and the EMS crew should be ready to provide resuscitative care if needed. An initial survey of the scene can offer important clues to help the paramedic formulate an impression. Initial size-up information that is useful in all EMS responses includes hazards and potential hazards, mechanism of injury or illness, and the number of patients at the scene.

Setting the Tone for the Patient Encounter

Two approaches in the primary survey set the tone for the patient encounter. The first is the resuscitative approach. The second is the contemplative approach. The **resuscitative approach** recognizes the need for immediate intervention for patients who have life-threatening illness or injury such as the following:

- Cardiorespiratory arrest
- Coma or altered level of consciousness
- Major trauma
- Possible cervical spine injury
- Respiratory distress or failure
- Seizures
- Shock or hypotension
- Unstable cardiac rhythms

If a life-threatening problem is present, the paramedic crew must take resuscitative action. History taking and other details should be delayed until immediate resuscitation measures have been provided. If immediate intervention to manage life threats is not required, the paramedic can use the **contemplative approach.** With this approach, the patient history is obtained and physical examination is performed before providing patient care.

In any patient care encounter, the paramedic may need to move the patient immediately to the emergency vehicle if any of the following occur:

- The paramedic cannot provide lifesaving interventions at the patient's side.
- The scene is too unstable or unsafe.
- The scene is too chaotic to allow thorough assessment.
- Inclement weather hinders assessment and care.

"Looking to Find"

Paramedics must find something before they can treat or report it. To find something, it must be suspected. Therefore during the primary survey, the paramedic must actively look for any problems that pose a threat to life. The assessment must be systematic so that the patient's chief complaint can be rapidly determined. The paramedic must then assess the degree of distress, obtain baseline vital signs, and stay focused on the patient's history and physical findings. A mental "rule-out list" often is a good approach in "looking to find." This is a list that considers the most serious problems *first* that could cause the patient's signs and symptoms.

Experience assists the paramedic in developing the ability for multitasking. In relation to health care, **multitasking** is the ability to ask questions, take notes, and perform tasks while listening to the patient's answers. In time the paramedic will gain the level of experience required for multitasking. Until then it is best to ask direct questions and then carefully listen to the patient's response. Important clues can be lost by not listening. If a particular task is required while the paramedic is obtaining a patient history, a partner should provide the patient care measure if possible. The patient's ability to describe symptoms and the paramedic's ability to listen may greatly influence the assessment. The paramedic should remember that the severity and location of the patient's pain may not always correlate well with some potentially life-threatening conditions. For example, a patient with myocardial infarction may at first complain of pain only in the arm or shoulder or some other minor discomfort (e.g., indigestion). The paramedic's role is to rapidly assess and provide treatment for the worst-case scenario.

BOX 59-3 Discrete Areas of Information

1. Patient identification, age, gender, and degree of distress
2. Chief complaint
3. Present illness or injury
   a. Pertinent details about the present problem
   b. Pertinent negatives (expected findings that are absent)
4. Medical history, including allergies and medications
5. Physical findings
   a. Vital signs
   b. Pertinent positive findings
   c. Pertinent negative findings
6. Assessment, including paramedic impression
7. Plan
   a. What has been done
   b. Orders requested

PRESENTING THE PATIENT

Presenting the patient in the course of out-of-hospital and in-hospital care is twofold. It refers to the skills of effective communication and to the effective transfer of patient information. Patient presentation is often a weak link in the chain of patient care despite its importance in every patient encounter.

The paramedic routinely provides patient presentation face to face, over the phone or radio, and in writing. These communication skills are essential and help the paramedic to establish trust and credibility with co-workers and other members of the health care teams. Good presentations suggest effective patient assessment and care to the listener, and vice versa. Poor presentation can compromise patient care. This may occur when the paramedic does not convey patient needs and status effectively to medical direction. As described in Chapter 17, the following are characteristics of an effective patient presentation:

- The presentation is concise, usually lasting less than 1 minute.
- The presentation is usually free of extensive medical jargon.
- The presentation follows the same basic information pattern.
- The presentation generally follows a standard format.
- The presentation includes pertinent findings and pertinent negatives.

When communicating a patient presentation, the paramedic should *begin the report with the end in mind*. For instance, the paramedic should anticipate discrete areas of information that others will question and be ready to provide those details (Box 59-3). Communicating a patient presentation requires experience. Until then, it may be best to use a preprinted card or other memory device (e.g., the SOAP format or similar method). These aids will help the paramedic to organize information and assessment findings.

CRITICAL THINKING

Can you think of any areas of improvement for your skills in "presenting the patient"?

SUMMARY

- Assessment-based management "puts it all together." This means that the paramedic gathers, evaluates, and synthesizes information. The paramedic makes proper decisions based on the information. Then the paramedic takes the appropriate actions required for the patient's care.
- Factors that can affect the quality of assessment and decision making include the paramedic's attitude, the patient's willingness to cooperate, distracting injuries, labeling and tunnel vision, the environment, patient compliance, and considerations of personnel availability.
- Promoting a coherent assessment is the goal. Thus members of the response team should have a preplan for determining roles and responsibilities.
- The paramedic crew should always be prepared for the worst event. They should carry essential equipment to manage every aspect of patient care.
- A calm and orderly manner is essential for the paramedic. This is especially the case when approaching a patient. During the initial assessment the paramedic must look actively for problems that pose a threat to life.
- Presenting the patient in the course of prehospital and hospital care is twofold. Presentation refers to the skills of effective communication. Presentation also refers to the effective transfer of patient information.

DRUG IDENTIFICATION GUIDE

The *Emergency Drug Index* is a list of commonly prescribed medications that are used in prehospital care; it is not intended to be a complete guide to all emergency medications. For additional drug information, consult other standard references. Drugs included in this index are listed alphabetically by generic name. Common trade names are shown in parentheses following the generic listing.

NOTE

The way in which drugs are packaged and supplied varies by manufacturer. It is important that paramedics verify how a particular drug is supplied by their EMS service. In addition, paramedics should verify the recommended dose or formula, know the indications and contraindications of any drug they administer, and take all safety precautions. Any concerns regarding the dose or administration of any drug should be guided by medical direction.

PREGNANCY CATEGORY RATINGS FOR DRUGS

Drugs have been categorized by the Food and Drug Administration according to the level of risk to the fetus. These categories are listed for each drug herein under "Pregnancy safety" and are interpreted as follows:

Category A: Controlled studies in women fail to demonstrate a risk to the fetus in the first trimester, and there is no evidence of risk in later trimesters; the possibility of fetal harm appears to be remote.

Category B: Either (1) animal reproductive studies have not demonstrated a fetal risk but there are no controlled studies in pregnant women or (2) animal reproductive studies have shown an adverse effect (other than decreased fertility) that was not confirmed in controlled studies on women in the first trimester and there is no evidence of risk in later trimesters.

Category C: Either (1) studies in animals have revealed adverse effects on the fetus and there are no controlled studies in women or (2) studies in women and animals are not available. Drugs in this category should be given only if the potential benefit justifies the risk to the fetus.

Category D: Positive evidence of human fetal risk exists, but the benefits for pregnant women may be acceptable despite the risk, as in life-threatening diseases for which safer drugs cannot be used or are ineffective. An appropriate statement must appear in the "Warnings" section of the labeling of drugs in this category.

Category X: Studies in animals or human beings have demonstrated fetal abnormalities, there is evidence of fetal risk based on human experience, or both; the risk of using the drug in pregnant women clearly outweighs any possible benefit. The drug is contraindicated in women who are or may become pregnant. An appropriate statement must appear in the "Contraindications" section of the labeling of drugs in this category.

ABCIXIMAB (REOPRO)

CLASS

Glycoprotein IIb/IIIa inhibitor

DESCRIPTION

Glycoprotein IIb/IIIa inhibitors inhibit the integrin GP IIb/IIIa receptor in the membrane of the platelets. As a result, they inhibit the common final pathway activation of platelet aggregation. Abciximab (in combination with aspirin and heparin) is indicated for use in patients undergoing PCI as well as for the treatment of unstable angina or NSTEMI infarction when PCI is planned within 24 hr.

ONSET AND DURATION

Onset: 2 hr

Duration: Platelet aggregation restored within 24-48 hr after infusion is stopped

INDICATIONS

Patients with NSTEMI, unstable angina, or PCI within 24 hr

CONTRAINDICATIONS

Active internal bleeding
Bleeding disorder
History of intracranial hemorrhage, neoplasm, AV malformation, aneurysm, or stroke within 2 years
Major surgical procedure or trauma within 6 weeks
Aortic dissection, pericarditis, and severe hypertension
Hypersensitivity to any GP IIb/IIIa inhibitor
Low platelet count (<100,000/mm^3)

ADVERSE REACTIONS

Anaphylactoid reaction/anaphylactic shock may occur
Bleeding (secondary to drug-induced platelet dysfunction)
GI bleeding
Hematemesis
Hematuria
Hypotension
Intracranial bleeding
Platelet dysfunction
Retroperitoneal bleeding
Stroke
Thrombocytopenia

DRUG INTERACTIONS

Concomitant use of other agents that may affect hemostasis, such as anticoagulants, other platelet inhibitors, NSAIDs, and thrombolytic agents, may be associated with an increased risk of bleeding.

HOW SUPPLIED

2 mg/mL (must be given with heparin)

DOSAGE AND ADMINISTRATION (ADULT)

PCI only: 0.25 mg/kg IV bolus (10-60 min before procedure); then 0.125 mcg/kg/min (max 10 mcg/min) IV infusion for 12 hr

ACS with planned PCI within 24 hr: 0.25 mg/kg IV bolus; then 10 mcg/min IV infusion for 18-24 hr, concluding 1 hr after PCI

SPECIAL CONSIDERATIONS

Pregnancy safety: Category C
Readministration may cause hypersensitivity reaction.

ACTIVATED CHARCOAL (ACTIDOSE-AQUA, ACTIDOSE, LIQUI-CHAR)

CLASS

Adsorbent, antidote

DESCRIPTION

Activated charcoal is a fine black powder that binds and adsorbs ingested toxins. Once the drug binds to the

activated charcoal, the combined complex is excreted in the feces.

ONSET AND DURATION

Onset: Immediate
Duration: Continual while in gastrointestinal tract; reaches equilibrium once saturated

INDICATIONS

Many oral poisonings and medication overdoses

CONTRAINDICATIONS

Corrosives, caustics, petroleum distillates (relatively ineffective and may induce vomiting)

ADVERSE REACTIONS

May indirectly induce nausea and vomiting.
May cause constipation or mild, transient diarrhea.

DRUG INTERACTIONS

Syrup of ipecac (adsorbed by activated charcoal and will result in vomiting of the charcoal)

HOW SUPPLIED

25 g (black powder)/25g/125mL bottle (200 mg/mL)
50 g (black powder)/50g/240ml bottle (200 mg/mL)
Other sizes include 15 g and 30 g, bottles and squeeze tubes. Most products come premixed (not powder) with water (aqueous preparations) or with sorbitol, a cathartic.

DOSAGE AND ADMINISTRATION

From 1 to 2 g/kg body mass (larger amounts if food is also present), prepared in a slurry and administered PO or slowly via nasogastric or orogastric tube
Adult: 30-100 g
Pediatric (1-12 yr): 15-30 g or 1-2 g/kg
Infant (less than 1 yr): 1 g/kg

SPECIAL CONSIDERATIONS

Pregnancy safety: Category C
Charcoal frequently is administered to pregnant patients, and the potential benefit versus risk is very high. Because charcoal remains within the gastrointestinal tract, its risk to the fetus virtually is eliminated, unless the charcoal and other stomach contents are aspirated.
Activated charcoal also may be known as "AC."
Activated charcoal is relatively insoluble in water.
Activated charcoal may blacken feces.
Activated charcoal must be stored in a closed container.
Different charcoal preparations may have varying adsorptive capacity.
Activated charcoal does not adsorb all drugs and toxic substances (e.g., phenobarbital, aspirin, cyanide, lithium, iron, lead, and arsenic).

ADENOSINE (ADENOCARD)

CLASS

Endogenous nucleoside, miscellaneous antidysrhythmic

DESCRIPTION

Adenosine primarily is formed from the breakdown of adenosine triphosphate. Adenosine triphosphate and adenosine are found in every cell of the human body and have a wide range of metabolic roles. Adenosine slows supraventricular tachycardias by decreasing electrical conduction through the atrioventricular node without causing negative inotropic effects. It also acts directly on sinus pacemaker cells and vagal nerve terminals to decrease chronotropic (heart rate) activity. First drug of choice for most forms of stable, narrow-complex SVT. May be considered for unstable narrow-complex reentry tachycardia while preparing for cardioversion. Adenosine does not convert atrial fibrillation, atrial flutter, or VT.

ONSET AND DURATION

Onset: Immediate
Duration: 10 sec

INDICATIONS

First drug for most forms of narrow-complex paroxysmal supraventricular tachycardia and dysrhythmias associated with bypass tracts such as Wolff-Parkinson-White (WPW) syndrome in adults and pediatric patients.
In undifferentiated regular stable wide-complex tachycardia, IV adenosine may be considered relatively safe. It may convert the rhythm to sinus, and may help diagnose the underlying rhythm.

CONTRAINDICATIONS

Drug-induced tachycardia
Second- or third-degree atrioventricular block
Hypersensitivity to adenosine
Atrial flutter, atrial fibrillation, ventricular tachycardia, WPW with atrial fibrillation/flutter. (Adenosine is not effective in converting these rhythms to sinus rhythm.)

ADVERSE REACTIONS

Facial flushing
Light-headedness
Paresthesias
Headache
Diaphoresis
Palpitations
Chest pain
Flushing
Hypotension

Shortness of breath
Transient periods of sinus bradycardia, sinus pause, or bradyasystole
Ventricular ectopy (fibrillation, flutter, tachycardia, torsades de pointes)
Nausea
Metallic taste

DRUG INTERACTIONS

Methylxanthines (e.g., caffeine and theophylline) antagonize the action of adenosine.
Dipyridamole potentiates the effect of adenosine; reduction of adenosine dose may be required.
Carbamazepine may potentiate the atrioventricular-nodal blocking effect of adenosine.

HOW SUPPLIED

Parenteral for IV injection
3 mg/mL in 2-mL and 5-mL flip-top vials

DOSAGE AND ADMINISTRATION

Adult: Initial dose: 6-mg rapid IV bolus over 1-3 sec, followed by a 20-mL saline bolus; then elevate extremity. A second dose (12 mg) may be given in 1-2 min if needed.
Injection technique: Place patient in mild reverse Trendelenburg position before drug administration. Record ECG during drug administration. Draw up adenosine and flush in 2 separate syringes. Attach both syringes to the IV injection port closest to the patient. Clamp IV tubing above injection port. Push adenosine as quickly as possible (1-3 sec). Maintain pressure on adenosine plunger while pushing saline flush as rapidly as possible after adenosine. Unclamp IV tubing.
Pediatric: Initial dose 0.1 mg/kg IV/IO (max single dose: 6 mg); second dose 0.2 mg/kg IV/IO rapid push; followed with 5-10 mL NS flush[1]

SPECIAL CONSIDERATIONS

Pregnancy safety: Category C
A brief period of asystole (up to 15 sec) following conversion, followed by resumption of normal sinus rhythm, is common after rapid administration.
Reduce initial dose to 3 mg in patients receiving dipyridamole or carbamazepine, in heart transplant patients, or if given by central venous access.
Patients taking theophylline or caffeine may require larger doses of adenosine.
Deterioration (including hypotension) may result if given for irregular, polymorphic wide-complex tachycardia/VT.
Adenosine may produce bronchoconstriction in patients with asthma and in patients with bronchopulmonary disease.

ALBUTEROL (PROVENTIL AND OTHERS)

CLASS

Sympathomimetic, bronchodilator, beta$_2$ agonist

DESCRIPTION

Albuterol is a sympathomimetic that is selective for beta$_2$-adrenergic receptors. It relaxes smooth muscles of the bronchial tree and peripheral vasculature by stimulating adrenergic receptors of the sympathetic nervous system.

ONSET AND DURATION

Onset: 5-8 min after inhalation
Duration: 2-6 hr after inhalation

INDICATIONS

Relief of bronchospasm in patients with reversible obstructive airway disease
Prevention of exercise-induced bronchospasm
Anaphylaxis
Hyperkalemia

CONTRAINDICATIONS

Prior hypersensitivity reaction to albuterol or levalbuterol
Cardiac dysrhythmias associated with tachycardia (precaution)

ADVERSE REACTIONS

Usually dose-related
Restlessness, apprehension
Dizziness
Palpitations, tachycardia
Dysrhythmias
Tremors

DRUG INTERACTIONS

Other sympathomimetics may exacerbate adverse cardiovascular effects.
MAO inhibitors and tricyclic antidepressants may potentiate effects on the vasculature (vasodilation).
Beta blockers may antagonize albuterol.
Albuterol may potentiate diuretic-induced hypokalemia.

HOW SUPPLIED

Metered-dose inhaler: 90 mcg/metered spray (17-g canister with 200 inhalations)
Solution for aerosolization: 0.5% (5 mg/mL); 0.083% (2.5 mg) in 3-mL unit dose/nebulizer

DOSAGE AND ADMINISTRATION

Bronchial Asthma/Anaphylaxis/Hyperkalemia
Adult:
Metered-dose inhaler: 1-2 inhalations (90-180 mcg) q 4-6 hr (wait 5 min between inhalations); max 12 inhalations/day

Solution: 2.5 mg (0.5 mL of 0.5% solution) diluted to 3 mL with 0.9% NS (0.083% solution); administer over 5-15 min; 3-4 times/day by nebulizer

NOTE: In settings of severe asthma exacerbation, 4 inhalations or 5 mg in 2.5-3 mL is indicated.

Pediatric:

Metered-dose inhaler: 4-8 puffs (inhalation) as needed, with spacer if not intubated

Solution: 0.01-0.03 mL (0.05-0.15 mg)/kg/dose to max of 0.50 mL/dose diluted in 2 mL of 0.9% NS; may be repeated q 20 min

Nebulized albuterol: <20 kg: 2.5 mg/dose (inhalation); >20 kg: 5 mg/dose (inhalation)

SPECIAL CONSIDERATIONS

Pregnancy safety: Category C

Albuterol may precipitate angina pectoris and dysrhythmias.

Albuterol should be used with caution in patients with diabetes mellitus, hyperthyroidism, prostatic hypertrophy, seizure disorder, or cardiovascular disorder.

In prehospital emergency care, albuterol should be administered only via inhalation.

ALTEPLASE (t-PA)

CLASS

Fibrinolytic

DESCRIPTION

Tissue plasminogen activator is a naturally occurring enzyme that has been mass-produced using recombinant DNA technology. The enzyme binds to fibrin-bound plasminogen at the site of an arterial clot, thus converting plasminogen to plasmin. Plasmin digests the fibrin strands of the clot, causing clot lysis and restoration of perfusion to the occluded artery. In prehospital care, fibrinolytic agents are used in treating selected patients with acute evolving myocardial infarction. (Other indications include ischemic stroke, deep vein thrombosis, peripheral artery embolism, IV catheter occlusion.)

ONSET AND DURATION

Onset: Clot lysis often occurs within 30 min.

Duration: 30-45 min (80% cleared in 10 min)

INDICATIONS

Acute evolving myocardial infarction

Massive pulmonary emboli

Deep venous thrombosis

Arterial thrombosis and embolism

To clear arteriovenous cannulae

Acute stroke

CONTRAINDICATIONS

Active bleeding or known bleeding disorder

Recent surgery (within 2-3 weeks)

Recent cerebrovascular accident

History of intracranial hemorrhage

Prolonged cardiopulmonary resuscitation

Recent intracranial or intraspinal surgery

Recent significant trauma (particularly head trauma)

Seizure at onset of stroke symptoms

Uncontrolled hypertension

Recent gastrointestinal bleeding

ADVERSE REACTIONS

Bleeding (gastrointestinal, genitourinary, intracranial, other sites)

Allergic reactions

Hypotension

Chest pain

Reperfusion dysrhythmias

Abdominal pain

DRUG INTERACTIONS

Acetylsalicylic acid may increase risk of bleeding (and may be beneficial in improving overall effectiveness).

Heparin and other anticoagulants also may increase risk of bleeding and improve overall effectiveness.

HOW SUPPLIED

50, 100 mg/vial with 50, 100 mL, and 2 mg (Cathflo) of diluent, respectively. May dilute further with equal amounts of 0.9% sodium chloride or D_5W.

DOSAGE AND ADMINISTRATION (BASED ON PATIENT'S WEIGHT)

Adult STEMI: Give 15 mg IV bolus, then 0.75 mg/kg over next 30 min (not to exceed 50 mg), and then 0.5 mg/kg over 60 min (not to exceed 35 mg); maximum total dose 100 mg. (Other doses may be prescribed by medical direction; different dosing is indicated for stroke.)

Pediatric: Safety not established

SPECIAL CONSIDERATIONS

Pregnancy safety: Category C

Obtain blood sample for coagulation studies before administration.

Gently roll—do not shake—the vial to mix powder with liquid.

Closely monitor vital signs.

Observe for bleeding.

Do not administer IM injections to patients receiving fibrinolytic drugs.

No arterial blood gas specimens should be drawn on potential fibrinolytic therapy candidates due to bleeding tendency.

Use caution when moving patient to avoid bleeding or bruising.

Use one IV line exclusively for fibrinolytic administration.

AMIODARONE (CORDARONE)

CLASS

Class III antidysrhythmic

DESCRIPTION

Amiodarone is a unique antidysrhythmic agent with multiple mechanisms of action. The drug prolongs the duration of the action potential and the effective refractory period, and when given short-term IV, probably includes noncompetitive beta-adrenergic receptor and calcium channel blocker activity.

ONSET AND DURATION

Onset: Within minutes
Duration: Variable

INDICATIONS (IV USE)

Initial treatment and prophylaxis of frequently recurring ventricular fibrillation and hemodynamically unstable ventricular tachycardia in patients unresponsive to shock delivery, CPR, and vasopressors
Recurrent hemodynamically unstable VT
Treatment of some stable atrial and ventricular dysrhythmias

CONTRAINDICATIONS

Pulmonary congestion
Cardiogenic shock
Second- or third-degree AV block if no pacemaker present
Bradycardia
Sensitivity to amiodarone or iodine

ADVERSE REACTIONS

Hypotension
Headache
Dizziness
Bradycardia
Atrioventricular conduction abnormalities
Flushing
Abnormal salivation
Pain at IV site
Liver function abnormalities
Congestive heart failure
Abnormal thyroid function

DRUG INTERACTIONS

May potentiate bradycardia and hypotension with beta blockers and calcium channel blockers.
May increase risk of atrioventricular block and hypotension with calcium channel blockers.
May increase anticoagulant effects of warfarin.
May decrease metabolism and increase serum levels of phenytoin, procainamide, quinidine, and theophyllines.
Routine use in combination with drugs that prolong the Q-T interval is not recommended.
Y-site incompatibilities with furosemide, heparin, and sodium bicarbonate

HOW SUPPLIED

50 mg/mL vials

DOSAGE AND ADMINISTRATION

Adult:
- Pulseless arrest unresponsive to CPR, shock, and vasopressors: 300 mg IV/IO push. If needed, second dose of 150 mg IV/IO push
- Life-threatening dysrhythmias: Max cumulative dose: 2.2 g IV/24 hr. May be given as rapid infusion 150 mg IV over first 10 min (15 mg/min) repeated every 10 min as needed. Slow infusion: 360 mg IV over 6 hr (1 mg/min). Maintenance infusion: 540 mg IV over 18 hr (0.5 mg/min)

Pediatric:
- Refractory VF, pulseless VT: 5 mg/kg rapid IV/IO bolus; can be repeated to total dose of 15 mg/kg (2.2 g in adolescents) IV per 24 hr; max single dose: 300 mg
- Perfusing supraventricular and ventricular dysrhythmias: Loading dose 5 mg/kg IV/IO over 20-60 min (max single dose: 300 mg); can repeat to a max of 15 mg/kg (2.2 g in adolescents) per day IV

SPECIAL CONSIDERATIONS

Pregnancy safety: Category D
Rapid infusion may cause hypotension.
Continuous electrocardiogram monitoring is required.
Slow infusion or discontinue if bradycardia or atrioventricular block occurs.
Do not give with other drugs that prolong Q-T interval (e.g., procainamide).
Maintain at room temperature and protect from excessive heat.

ASPIRIN (ASA, BAYER, ECOTRIN, ST. JOSEPH, OTHERS)

CLASS

Analgesic, antiinflammatory, antipyretic, antiplatelet

DESCRIPTION

Aspirin decreases inflammation (analgesic effect not limited to effects in CNS), dilates peripheral vessels, and decreases platelet aggregation. The use of aspirin is strongly recommended for all patients with acute coronary syndrome.

ONSET AND DURATION

Onset: 15-30 min
Duration: 4-6 hr

INDICATIONS

Mild to moderate pain or fever
Prevention of platelet aggregation in ischemia and thromboembolism
All patients with ACS
Any patient with symptoms of ischemic chest pain

Unstable angina
Prevention of myocardial infarction or reinfarction

CONTRAINDICATIONS

Hypersensitivity to salicylates
Gastrointestinal bleeding
Active ulcer disease or acute asthma (relative contraindication)
Hemorrhagic stroke
Bleeding disorders
Children with flulike symptoms

ADVERSE REACTIONS

Stomach irritation
Heartburn or indigestion
Nausea or vomiting
Allergic reaction

DRUG INTERACTIONS

Decreased effects with antacids and steroids
Increased effects with anticoagulants, insulin, oral hypoglycemics, fibrinolytic agents

HOW SUPPLIED

Tablets (65, 81, 325, 500, 650, 975 mg)
Capsules (325, 500 mg)
Controlled-release tablets (800 mg)
Suppositories (varies from 60 mg to 1.2 g)

DOSAGE AND ADMINISTRATION

Adult: Mild pain and fever: 325-650 mg PO q 4 hr
ACS: 160-325 mg PO non–enteric-coated tablet (chewing is preferable to swallowing); may use rectal suppository for patients who cannot take orally
Pediatric: Not indicated in prehospital setting

SPECIAL CONSIDERATIONS

Pregnancy safety: Category D in third trimester, Category C in first and second trimesters
Should be given as soon as possible to the patient with ACS.

ATENOLOL (TENORMIN)

CLASS

Beta-blocking agent

DESCRIPTION

Atenolol competes with beta-adrenergic agonists for available beta-receptor sites on the membranes of cardiac muscle, bronchial smooth muscle, and the smooth muscle of blood vessels. The $beta_1$-blocking action on the heart decreases heart rate, conduction velocity, myocardial contractility, and cardiac output. Atenolol is used to control ventricular response in supraventricular tachydysrhythmias (paroxysmal supraventricular tachycardia, atrial fibrillation, atrial flutter). Atenolol is considered a second-line agent after adenosine, diltiazem, or digitalis derivative.

ONSET AND DURATION

Onset: Within 10 min (IV)
Duration: 2-4 hr

INDICATIONS

All patients with suspected MI and unstable angina in the absence of contraindications (can reduce the incidence of VF)
Useful as an adjunctive agent with fibrinolytic therapy (may reduce nonfatal reinfarction and recurrent ischemia)
To convert to normal sinus rhythm or to slow ventricular response (or both) in supraventricular tachydysrhythmias (reentry SVT, atrial fibrillation, or atrial flutter)
To reduce myocardial ischemia in AMI patients with elevated heart rate, blood pressure, or both

CONTRAINDICATIONS

Hemodynamically unstable patients
STEMI if signs of heart failure, low cardiac output, or increased risk for cardiogenic shock are present
Relative contraindications include P-R interval >0.24 sec, second- or third-degree heart block, active asthma, reactive airway disease, severe bradycardia, SBP <100 mm Hg.
Not available intravenously in the United States

ADVERSE REACTIONS

Bradycardia
Atrioventricular conduction delays
Hypotension
Bronchospasm

DRUG INTERACTIONS

Atenolol may potentiate antihypertensive effects when given to patients taking calcium channel blockers or MAO inhibitors; catecholamine-depleting drugs may potentiate hypotension; sympathomimetic effects may be antagonized; signs of hypoglycemia may be masked.

HOW SUPPLIED

5 mg in 10-mL ampules (injectable form is not available in the United States)

DOSAGE AND ADMINISTRATION

Adult: 5 mg slow IV (over 5 min); wait 10 min and then give second dose of 5 mg over 5 min
Pediatric: Not recommended

SPECIAL CONSIDERATIONS

Pregnancy safety: Category C
Atenolol must be given slowly IV over 5 min.
Concurrent IV administration with IV calcium channel blockers such as verapamil or diltiazem can cause severe hypotension.
Atenolol should be used with caution in persons with liver or renal dysfunction.

ATROPINE SULFATE (ATROPINE AND OTHERS)

CLASS

Anticholinergic agent

DESCRIPTION

Atropine sulfate (a potent parasympatholytic) inhibits actions of acetylcholine at postganglionic parasympathetic (primarily muscarinic) receptor sites. Small doses inhibit salivary and bronchial secretions; moderate doses dilate pupils and increase heart rate. Large doses decrease gastrointestinal motility, inhibit gastric acid secretion, and may block nicotinic receptor sites at the autonomic ganglia and at the neuromuscular junction. Blocked vagal effects result in increased heart rate and enhanced atrioventricular conduction with limited or no inotropic effect. In emergency care, atropine primarily is used to increase the heart rate in life-threatening or symptomatic bradycardia and to antagonize excess muscarinic receptor stimulation caused by organophosphate insecticides or chemical nerve agents (e.g., sarin and soman).

ONSET AND DURATION

Onset: Rapid
Duration: 2-6 hr

INDICATIONS

Hemodynamically significant bradycardia
Organophosphate or nerve gas poisoning

CONTRAINDICATIONS

Tachycardia
Hypersensitivity to atropine
Use with caution in patients with myocardial ischemia and hypoxia
Avoid in hypothermic bradycardia
Obstructive disease of gastrointestinal tract
Obstructive uropathy
Unstable cardiovascular status in acute hemorrhage with myocardial ischemia
Narrow-angle glaucoma
Thyrotoxicosis

ADVERSE REACTIONS

Tachycardia
Paradoxical bradycardia when pushed too slowly or when used at doses less than 0.5 mg
Palpitations
Dysrhythmias
Headache
Dizziness
Anticholinergic effects (dry mouth/nose/skin, photophobia, blurred vision, urinary retention, constipation)
Nausea and vomiting
Flushed, hot, dry skin
Allergic reactions

DRUG INTERACTIONS

Use with other anticholinergic agents may increase vagal blockade.
Potential adverse effects may occur when administered with digitalis, cholinergics, neostigmine.
The effects of atropine may be enhanced by antihistamines, procainamide, quinidine, antipsychotics and antidepressants, and thiazides.
Increased toxicity: amantadine

HOW SUPPLIED

Parenteral: There are various injection preparations.
In emergency care, atropine usually is supplied in prefilled syringes containing 1 mg in 10 mL of solution.

DOSAGE AND ADMINISTRATION

Bradydysrhythmia (With or Without ACS)
Adult: 0.5 mg every 3-5 min for desired response (max total dose: 3 mg); use shorter dosing intervals (3 min) and higher doses in severe clinical conditions
Pediatric: 0.02 mg/kg IV/IO; min dose: 0.1 mg; max single dose of 0.5 mg; may be repeated once; max total dose for a child: 1 mg; for adolescent: 3 mg; ET dose is 0.04-0.06 mg/kg
Anticholinesterase Poisoning
Adult: 1-2 mg IV push every 5-15 min until atropine effects are observed; then every 1-4 hr for at least 24 hr; extremely large doses (2-4 mg or more) may be needed
Pediatric: <12 years: 0.02-0.05 mg/kg/dose IV/IO; may be repeated every 20-30 min until muscarinic symptoms reverse; >12 years: 2 mg IV/IO; then 1-2 mg IV/IO every 20-30 min until muscarinic symptoms reverse
Rapid Sequence Intubation
0.01-0.02 mg/kg IV/IO; max single dose: 0.5 mg

SPECIAL CONSIDERATIONS

Pregnancy safety: Category C
Follow endotracheal tube administration with several positive pressure ventilations.
Atropine causes pupillary dilation, rendering the pupils nonreactive; pupil response may not be useful in monitoring central nervous system status.

CALCIUM CHLORIDE

CLASS

Electrolyte

DESCRIPTION

Calcium is an essential component for the functional integrity of the nervous and muscular systems, for normal cardiac contractility, and for the coagulation of blood. Calcium chloride contains 27.2% elemental calcium. Calcium chloride is a hypertonic solution and should be administered only IV (slowly, not exceeding 1 mL/min).

ONSET AND DURATION

Onset: 5-15 min
Duration: Dose-dependent (effects may persist for 4 hr after IV administration)

INDICATIONS

Hyperkalemia (except when associated with digitalis toxicity)
Hypocalcemia (e.g., after multiple blood transfusions)
Calcium channel blocker toxicity
Hypermagnesemia
To prevent hypotensive effects of calcium channel blocking agents (e.g., IV verapamil and diltiazem)

CONTRAINDICATIONS

Ventricular fibrillation during cardiac resuscitation
In patients with digitalis toxicity
Hypercalcemia

ADVERSE REACTIONS

Bradycardia (may cause asystole)
Hypotension
Metallic taste
Severe local necrosis and sloughing following intramuscular use or IV infiltration

DRUG INTERACTIONS

Calcium may worsen dysrhythmias caused by digitalis.
Calcium may antagonize the peripheral vasodilatory effects of calcium channel blockers.

HOW SUPPLIED

10% solution in 10-mL (100 mg/mL) ampules, vials, and prefilled syringes

DOSAGE AND ADMINISTRATION

Hyperkalemia and Calcium Channel Blocker Overdose
Adult: Typical dose is 500-1000 mg (5-10 mL of a 10% solution); may be repeated as needed
Pediatric: 20 mg/kg (0.2 mL/kg) IV of 10% solution slow IV/IO; may repeat if documented or clinical indication persists (e.g., toxicological problem); dose should not exceed adult dose

SPECIAL CONSIDERATIONS

Pregnancy safety: Category C
Calcium may produce vasospasm in coronary and cerebral arteries.
Do not use routinely in cardiac arrest.
Hypertension and bradycardia may occur with rapid administration.
Monitor heart rate during administration.

NOTE
It is important to flush the IV line between administration of calcium chloride and sodium bicarbonate to avoid precipitation.

DEXAMETHASONE (DECADRON, HEXADROL, AND OTHERS)

CLASS

Glucocorticoid

DESCRIPTION

Dexamethasone is a synthetic steroid that is related chemically to the natural hormones secreted by the adrenal cortex. The drug suppresses acute and chronic inflammation, potentiates the relaxation of vascular and bronchial smooth muscle by beta-adrenergic agonists, and possibly alters airway hyperreactivity. In emergency care, dexamethasone generally is used in the treatment of allergic reactions and asthma and to reduce swelling in the central nervous system.

ONSET AND DURATION

Onset: 4-8 hr after parenteral administration
Duration: 24-72 hr

INDICATIONS

Endocrine, rheumatic, hematological disorders
Allergic states
Septic shock
Chronic inflammation

CONTRAINDICATIONS

Hypersensitivity to the product
Active untreated infections (relative)

ADVERSE REACTIONS

Decreased wound healing
Hypertension
Gastrointestinal bleeding
Hyperglycemia

DRUG INTERACTIONS

Barbiturates and phenytoin can decrease dexamethasone effects.

HOW SUPPLIED

Common preparations used in emergency care are for IV administration and are as follows:
4 mg/mL in 1-, 5-, 10-, 25-, 30-mL vials
10 mg/mL in 10-mL vials, 1-mL syringe, 1-mL ampule

20 mg/mL in 5-mL vials (IV or IM), 5-mL syringe (IV)
24 mg/mL (IV only) in 5- and 10-mL vials

DOSAGE AND ADMINISTRATION

Adult: There is considerable variance in recommended dexamethasone doses. The usual range in emergency care is 4-24 mg IV. Some physicians may prefer significantly higher doses (up to 100 mg) for unusual indications.
Pediatric: 1 dose of 0.6 mg/kg PO/IM/IV (max dose: 16 mg)

SPECIAL CONSIDERATIONS

Pregnancy safety: Category C; dexamethasone crosses the placenta and may cause fetal damage.
Medication should be protected from heat.
Because of onset of action (4-8 hr), dexamethasone should not be considered a first-line medication for allergic reactions.

DEXTROSE 50%

CLASS

Carbohydrate, hypertonic solution

DESCRIPTION

The term *dextrose* is used to describe the six-carbon sugar *D-glucose,* the principal form of carbohydrate used by the body. 50% dextrose solution is used in emergency care to treat hypoglycemia and in the management of coma of unknown origin.

ONSET AND DURATION

Onset: 1 min
Duration: Depends on the degree of hypoglycemia

INDICATIONS

Hypoglycemia (documented or strongly suspected)
Altered level of consciousness
Coma of unknown origin
Seizure of unknown origin

CONTRAINDICATIONS

Intracranial hemorrhage
Increased intracranial pressure
Known or suspected stroke in the absence of hypoglycemia

ADVERSE REACTIONS

Warmth, pain, burning from medication infusion, hyperglycemia, thrombophlebitis

DRUG INTERACTIONS

None significant

HOW SUPPLIED

25 g/50 mL prefilled syringe (500 mg/mL)

DOSAGE AND ADMINISTRATION

Adult: 12.5-25 g slow IV; may be repeated once
Pediatric: 0.5-1 g/kg IV/IO (max recommended concentration: 25%)
2-4 mL/kg 25%
5-10 mL/kg 10%
10-20 mL/kg 5% if volume tolerated

SPECIAL CONSIDERATIONS

Pregnancy safety: Category C
Draw blood sample before administration if possible.
Perform blood glucose analysis before administration if possible.
Extravasation may cause tissue necrosis; use large vein and aspirate occasionally to ensure route patency.
50% dextrose solution sometimes may precipitate severe neurological symptoms (Wernicke's encephalopathy) in thiamine-deficient patients (for example, alcoholics). (This can be prevented by administering 100 mg of thiamine IV.)

DIAZEPAM (VALIUM AND OTHERS)

CLASS

Benzodiazepine

DESCRIPTION

Diazepam is a frequently prescribed medication to treat anxiety and stress. In emergency care, diazepam is used to treat alcohol withdrawal and grand mal seizure activity. Diazepam acts on the limbic, thalamic, and hypothalamic regions of the central nervous system to potentiate the effects of inhibitory neurotransmitters, raising the seizure threshold in the motor cortex. It also may be used in conscious patients during cardioversion and transcutaneous pacing to induce amnesia and sedation. Its use as an anticonvulsant may be short-lived because of rapid redistribution from the central nervous system. Rapid IV administration may be followed by respiratory depression and excessive sedation, particularly in elderly patients.

ONSET AND DURATION

Onset: (IV) 1-5 min; (IM) 15-30 min
Duration: (IV) 15 min-1 hr; (IM) 15 min-1 hr

INDICATIONS

Acute anxiety states
Acute alcohol withdrawal
Skeletal muscle relaxation
Seizure activity
Premedication before countershock or transcutaneous pacing

CONTRAINDICATIONS

Hypersensitivity to the drug
Substance abuse (use with caution)

Coma (unless the patient has seizures or severe muscle rigidity or myoclonus)
Shock
Central nervous system depression as a result of head injury
Respiratory depression

ADVERSE REACTIONS

Hypotension
Reflex tachycardia (rare)
Respiratory depression
Ataxia
Psychomotor impairment
Confusion
Nausea
Dizziness
Drowsiness
Blurred vision

DRUG INTERACTIONS

Diazepam may precipitate central nervous system depression and psychomotor impairment when the patient is taking other central nervous system depressant medications.
Diazepam should not be administered with other drugs because of possible precipitation (incompatible with most fluids; should be administered into an IV of NS solution).

HOW SUPPLIED

Parenteral: 5 mg/mL vials, ampules, Tubex

DOSAGE AND ADMINISTRATION

Seizure Activity
Adult: 5 mg over 2 min (up to 10 mg for most adults) IV q 10-15 min prn (max dose: 30 mg)
Pediatric: Dose for infants 30 days to 5 yr is 0.2-0.5 mg slow IV q 2-5 min to max 5 mg; children 5 yr or older is 1 mg q 2-5 min to max 10 mg slow IV
Premedication for Cardioversion or Transcutaneous Pacing
Adult: 5-15 mg IV, 5-10 min before procedure
Rapid Sequence Intubation in Children
0.2-0.3 mg/kg IV/IO; max single dose 10 mg

SPECIAL CONSIDERATIONS

Pregnancy safety: Category D
Diazepam may cause local venous irritation.
Diazepam has short duration of anticonvulsant effect.
Reduce dose by 50% in elderly patients.
Rectal administration may require higher dose because absorption is incomplete.
Resuscitation equipment should be readily available.

DIGOXIN (LANOXIN)

CLASS

Cardiac glycoside, miscellaneous antidysrhythmic

DESCRIPTION

Digoxin (digitalis) is a cardiac glycoside derived primarily from the foxglove plant. Its primary action involves alteration of ion transport across cardiac cell membranes. Increased intracellular calcium improves myocardial contractility. Digoxin increases vagal tone and therefore indirectly decreases sinus node rate, reduces sympathetic tone, and decreases atrioventricular node conduction velocity (with an increase in atrioventricular node refractory period). Sodium pumped out of cells may cause increased automaticity.

ONSET AND DURATION

Onset: (IV) 5-30 min
Duration: 3-4 days

INDICATIONS (MAY BE OF LIMITED USE)

Supraventricular tachycardias, especially atrial flutter and atrial fibrillation
Alternative drug for reentry SVT

CONTRAINDICATIONS

Ventricular fibrillation
Ventricular tachycardia
Atrioventricular block
Digitalis toxicity
Hypersensitivity to digoxin
Second- or third-degree heart block in the absence of artificial pacing

ADVERSE REACTIONS (MOSTLY RELATED TO DIGITALIS TOXICITY)

Headache
Weakness
Visual disturbances (blurred, yellow or green vision)
Confusion
Seizures
Dysrhythmias (virtually any disturbance, but junctional tachycardias are most common)
Nausea and vomiting
Skin rash
Hypotension

DRUG INTERACTIONS

Amiodarone, verapamil, and quinidine may increase serum digoxin concentrations by 50% to 70%.
Concurrent administration of IV digoxin and IV verapamil may lead to severe heart block.
Erythromycin and tetracycline may increase serum digoxin concentrations by reducing hepatic breakdown.
Diuretics may potentiate digoxin cardiotoxicity via loss of potassium.

Sympathomimetics may augment the inotropic and cardiotoxic effects of digoxin.
Concomitant administration of kaolin, pectin, and antacids may reduce digoxin absorption from the gastrointestinal tract.

HOW SUPPLIED

In emergency care, the common form of digoxin is supplied in 2-mL ampules, containing 0.5 mg of the drug (0.25 mg/mL)

DOSAGE AND ADMINISTRATION

Adult: Loading dose 0.004-0.006 mg/kg (4-6 mcg/kg) initially over 5 min; second and third boluses of 0.002-0.003 mg/kg (2-3 mcg/kg) to follow at 4-8 hr intervals (total loading dose 8-12 mcg/kg divided over 8-16 hr); maintenance dose affected by body mass and renal function
Pediatric: Not recommended in prehospital setting

SPECIAL CONSIDERATIONS

Pregnancy safety: Category C
Patient should be monitored constantly for signs of digitalis toxicity.
Patients with myocardial infarction and/or renal failure are prone to developing digitalis toxicity.
Digitalis toxicity is potentiated in patients with hypokalemia, hypomagnesemia, and hypercalcemia.
Avoid use in patients with Wolff-Parkinson-White syndrome because of possible ventricular dysrhythmias.
Avoid electrical cardioversion if patient is receiving digoxin unless condition is life threatening; use lower dose (10-20 J).
Reduce dose by 50% when used with amiodarone.

DIGOXIN IMMUNE FAB (DIGIBIND, DIGIFAB)

CLASS

Biologic response modifier; antidote

DESCRIPTION

Digoxin immune Fab (ovine) is a protein that consists of antibody fragments, which are used as an antidote for digitalis toxicity. Molecules of digoxin or digitoxin are removed from tissue binding sites and are sequestered in the extracellular fluid, shifting equilibrium away from binding of the drug to its tissue receptors.[2]

ONSET AND DURATION

Onset: Within minutes
Duration: Dose-dependent

INDICATIONS

Digoxin toxicity with:
Life-threatening dysrhythmias
Shock or congestive heart failure
Hyperkalemia (potassium level >5 mEq/L)

CONTRAINDICATIONS

Ovine protein hypersensitivity
Use with caution in patients with renal failure or renal impairment.

ADVERSE REACTIONS

Anaphylaxis
Atrial fibrillation
Heart failure
Hypokalemia
Hypotension
Injection site reaction
Phlebitis

DRUG INTERACTIONS

None known

HOW SUPPLIED

38 mg (Digibind) and 40 mg (DigiFab) powder for IV injection

DOSAGE AND ADMINISTRATION

Adults and children: Dose varies according to amount of digoxin ingested. (Each vial binds about 0.5 mg of digoxin.) Average dose is 10 vials (400 mg); may require up to 20 vials (800 mg). For chronic intoxication 3-5 vials may be effective. Monitor children for volume overload.

SPECIAL CONSIDERATIONS

Pregnancy safety: Category C
Visually inspect parenteral products for particulate matter and discoloration before administration whenever solution and container permit.
Closely monitor the patient's temperature, blood pressure, and ECG.

DILTIAZEM (CARDIZEM) INJECTABLE

CLASS

Calcium channel blocker or calcium channel antagonist

DESCRIPTION

Diltiazem is a calcium channel blocking agent that slows conduction, increases refractoriness in the atrioventricular node, and causes coronary and peripheral vasodilation. The drug is used to control ventricular response rates in patients with atrial fibrillation or flutter, multifocal atrial tachycardias. Use after adenosine to treat refractory reentry SVT in patients with narrow QRS complex and adequate blood pressure.

ONSET AND DURATION

Onset: 2-5 min
Duration: 1-3 hr

INDICATIONS

To control ventricular rate in atrial fibrillation and atrial flutter
Multifocal atrial tachycardias
Paroxysmal supraventricular tachycardia

CONTRAINDICATIONS

Wide QRS tachycardias of unknown origin or poison/drug-induced tachycardia
Sick sinus syndrome
Second- or third-degree atrioventricular block (except with a functioning pacemaker)
Hypotension (less than 90 mm Hg)
Cardiogenic shock
Hypersensitivity to diltiazem
Rapid atrial fibrillation or atrial flutter associated with Wolff-Parkinson-White syndrome or a short P-R interval syndrome
Ventricular tachycardia
Acute myocardial infarction

ADVERSE REACTIONS

Atrial flutter
First- and second-degree atrioventricular block
Bradycardia
Hypotension
Chest pain
Congestive heart failure
Peripheral edema
Syncope
Ventricular dysrhythmias
Sweating
Nausea and vomiting
Dizziness
Dry mouth
Dyspnea
Headache
Rash

DRUG INTERACTIONS

Caution is warranted in patients receiving medications that affect cardiac contractility and/or sinoatrial or atrioventricular node conduction.
Diltiazem is incompatible with simultaneous furosemide injection.

HOW SUPPLIED

25 mg (5-mL vial); 50 mg (10-mL vial)

DOSAGE AND ADMINISTRATION

Acute rate control: 0.25 mg/kg (15-20 mg for the average patient) IV over 2 min; may be repeated in 15 min (0.35 mg/kg; 20-25 mg for the average patient) IV over 2 min
Maintenance infusion: Dilute 125 mg (25 mL) in 100 mL of solution (NS or D_5W); infuse 5-15 mg/hr, titrated to heart rate
Pediatric: Safety not established

SPECIAL CONSIDERATIONS

Pregnancy safety: Category C
Use with caution in patients with impaired renal or hepatic function.
Hypotension occasionally may result (more common with verapamil); carefully monitor vital signs.
Concurrent IV administration with IV beta blockers can cause severe hypotension and AV block. Use caution in patients taking oral beta blockers.
Premature ventricular contractions may be present on conversion of paroxysmal supraventricular tachycardia to sinus rhythm.
Shelf-life at room temperature is 1 month.

DIPHENHYDRAMINE (BENADRYL)

CLASS

Antihistamine

DESCRIPTION

Antihistamines prevent the physiological actions of histamine by blocking H_1 (e.g., diphenhydramine and cimetidine) and H_2 (e.g., cimetidine, ranitidine, and famotidine) receptor sites. Antihistamines are indicated for conditions in which histamine excess is present (e.g., acute urticaria) and are used as adjunctive therapy (with epinephrine, for example) in the treatment of anaphylactic shock. Antihistamines also are effective in the treatment of certain extrapyramidal (dystonic) reactions and for relief of upper respiratory tract and sinus symptoms associated with allergic reactions.

ONSET AND DURATION

Onset: Max effects 1-3 hr
Duration: 6-12 hr

INDICATIONS

Moderate to severe allergic reactions (after epinephrine)
Anaphylaxis
Acute extrapyramidal (dystonic) reactions

CONTRAINDICATIONS

Patients taking non-selective MAO inhibitors
Hypersensitivity
Narrow-angle glaucoma (relative)
Newborns and nursing mothers

ADVERSE REACTIONS

Dose-related drowsiness
Disturbed coordination

Hypotension
Palpitations
Tachycardia, bradycardia
Thickening of bronchial secretions
Dry mouth and throat
Paradoxical excitement in children

DRUG INTERACTIONS

Central nervous system depressants may increase depressant effects.
MAO inhibitors may prolong and intensify anticholinergic effects of antihistamines.

HOW SUPPLIED

Parenteral: 10 and 50 mg/mL vials, prefilled syringe

DOSAGE AND ADMINISTRATION

Adult: The standard dose of diphenhydramine is 10-50 mg IM, slow IV q 6-8 hr (max: 400 mg/day)
Pediatric (greater than 10 kg): 1.25 mg/kg/dose q 6 hr (max: 300 mg/day)

SPECIAL CONSIDERATIONS

Pregnancy safety: Category C
Use cautiously in patients with central nervous system depression or lower respiratory tract diseases such as asthma.

DOBUTAMINE (DOBUTREX)

CLASS

Sympathomimetic

DESCRIPTION

Dobutamine is a synthetic catecholamine that primarily stimulates $beta_1$-adrenergic receptors, and has much less significant effects on $beta_2$- and alpha-adrenergic receptors. The clinical effects of this drug include positive inotropic effects with minimal changes in chronotropic activity or systemic vascular resistance. For these reasons, dobutamine is useful in the management of congestive heart failure when an increase in heart rate is not desired.

ONSET AND DURATION

Onset: 1-2 min; peak after 10 min
Duration: 10-15 min

INDICATIONS

Pump problems (CHF, pulmonary congestion) with SBP of 70-100 mm Hg and *no* signs of shock

CONTRAINDICATIONS

Tachydysrhythmias (atrial fibrillation, atrial flutter)
Severe hypotension with signs of shock
Idiopathic hypertrophic subaortic stenosis
Suspected or known drug-induced shock

ADVERSE REACTIONS

Anxiety
Headache
Nausea
Fluctuations in blood pressure
Dose-related tachydysrhythmias
Hypertension
Ventricular ectopy

DRUG INTERACTIONS

Beta-adrenergic antagonists may blunt inotropic responses.
Sympathomimetics and phosphodiesterase inhibitors may exacerbate dysrhythmia responses.
Dobutamine is incompatible with sodium bicarbonate and furosemide in same IV line; it may be given in separate IV lines.

HOW SUPPLIED

12.5 mg/mL injectable

DOSAGE AND ADMINISTRATION

Adult: Usual dose is 2-20 mcg/kg/min IV, based on inotropic effect; titrate so heart rate does not increase by >10% of baseline
Pediatric: 2-20 mcg/kg/min IV/IO, titrated to desired effect

SPECIAL CONSIDERATIONS

Pregnancy safety: Category C
Administer via an infusion pump to ensure precise flow rates.
Blood pressure should be monitored closely; hemodynamic monitoring is recommended for optimal use.
Dobutamine may be administered through a Y-site with concurrent dopamine, lidocaine, nitroprusside, and potassium chloride infusions; do not mix with sodium bicarbonate.
Increases in heart rate of more than 10% may induce or exacerbate myocardial ischemia.
Lidocaine should be readily available.
Correct hypovolemia before using dobutamine in hypotensive patients.
Elderly patients may have significantly decreased responses.

DOPAMINE (INTROPIN)

CLASS

Sympathomimetic

DESCRIPTION

Dopamine is related chemically to epinephrine and norepinephrine. It acts primarily on $alpha_1$- and $beta_1$-adrenergic receptors in a dose-dependent fashion. At moderate doses ("cardiac doses"), dopamine stimulates beta-adrenergic receptors, causing enhanced myocardial contractility, increased cardiac output, and a rise in blood pressure. At

high doses ("vasopressor doses"), dopamine has an alpha-adrenergic effect, producing peripheral arterial and venous constriction. Dopamine is a second-line drug for symptomatic bradycardia (after atropine). It commonly is used in the treatment of hypotension (SBP <70-100 mm Hg) with signs and symptoms of shock.

ONSET AND DURATION

Onset: 2-4 min
Duration: 10-15 min

INDICATIONS

Hemodynamically significant hypotension in the absence of hypovolemia
Symptomatic bradycardia (second-line drug after atropine)

CONTRAINDICATIONS

Tachydysrhythmias
Ventricular fibrillation
Patients with pheochromocytoma

ADVERSE REACTIONS

Dose-related tachydysrhythmias
Hypertension
Increased myocardial oxygen demand (e.g., ischemia)
Headache
Anxiety
Nausea and vomiting

DRUG INTERACTIONS

Dopamine may be deactivated by alkaline solutions (sodium bicarbonate and furosemide).
MAO inhibitors may potentiate the effect of dopamine.
Sympathomimetics and phosphodiesterase inhibitors exacerbate dysrhythmia response.
Beta-adrenergic antagonists may blunt inotropic response.
When administered with phenytoin, hypotension, bradycardia, and seizures may develop.

HOW SUPPLIED

200, 400, 800 mg in 5-mL prefilled syringe and ampule for IV infusion (IV piggyback)

DOSAGE AND ADMINISTRATION

Adult: Usual infusion rate 2-20 mcg/kg/min; titrate to response; taper slowly
Pediatric: 2-20 mcg/kg/min IV/IO, titrated to patient response (not to exceed 20 mcg/kg/min); if infusion dose >20 mcg/kg/min is required, consider alternative adrenergic agent (e.g., epinephrine/norepinephrine)

SPECIAL CONSIDERATIONS

Pregnancy safety: Category C
Infuse through large, stable vein to avoid the possibility of extravasation injury.
Use infusion pump to ensure precise flow rates.
Monitor patient for signs of compromised circulation.
Correct hypovolemia before using dopamine in hypotensive patients.
Do not mix with sodium bicarbonate.

EPINEPHRINE (ADRENALIN)

CLASS

Sympathomimetic

DESCRIPTION

Epinephrine is an endogenous catecholamine that directly stimulates alpha-, $beta_1$-, and $beta_2$-adrenergic receptors in dose-related fashion. Epinephrine is the initial drug of choice for treating bronchoconstriction and hypotension resulting from anaphylaxis and all forms of cardiac arrest. Epinephrine is useful in the management of reactive airway disease, but beta-adrenergic agents usually are considered the drugs of choice because they are inhaled and have fewer side effects. Rapid injection produces a rapid increase in blood pressure, ventricular contractility, and heart rate. In addition, epinephrine causes vasoconstriction in the arterioles of the skin, mucosa, and splanchnic areas, and antagonizes the effects of histamine.

ONSET AND DURATION

Onset: (subQ) 5-10 min; (IV/endotracheal tube) 1-2 min
Duration: 5-10 min

INDICATIONS

Acute allergic reaction (anaphylaxis)
Cardiac arrest
Pulseless electrical activity
Ventricular fibrillation and pulseless ventricular tachycardia unresponsive to initial defibrillation
Symptomatic bradycardia
Severe hypotension accompanied by bradycardia when pacing and atropine fail
Bronchial asthma

CONTRAINDICATIONS

Hypersensitivity (not an issue especially in emergencies—the dose should be lowered or given slowly in non–cardiac arrest patients with heart disease)
Hypovolemic shock (as with other catecholamines, correct hypovolemia before use)
Coronary insufficiency (use with caution)

ADVERSE REACTIONS

Headache
Nausea and vomiting
Restlessness
Weakness
Dysrhythmias, including ventricular tachycardia and ventricular fibrillation
Hypertension
Precipitation of angina pectoris

Tachycardia
Tremors
Dyspnea

DRUG INTERACTIONS

MAO inhibitors may potentiate the effect of epinephrine.
Beta-adrenergic antagonists may blunt inotropic response.
Sympathomimetics and phosphodiesterase inhibitors may exacerbate dysrhythmia response.
May be deactivated by alkaline solutions (sodium bicarbonate, furosemide).

HOW SUPPLIED

Parenteral: 1 mg/mL (1:1000), 0.1 mg/mL (1:10,000) ampule and prefilled syringe
Autoinjector (EpiPen): 0.3 mg/mL (1:2000)

DOSAGE AND ADMINISTRATION

Profound Bradycardia or Hypotension
Adult: 2-10 mcg/min infusion; titrate to patient response
Pediatric: All IV/IO doses: 0.01 mg/kg (1:10,000, 0.1 mL/kg); continuous infusion: 0.1-1 mcg/kg/min; higher doses may be effective
All ET doses: 0.1 mg/kg (0.1 mL/kg of 1:1000)
Pulseless Arrest
Adult:[1]
IV/IO dose: 1 mg (10 mL, 1:10,000) IV/IO push or endotracheal tube (2-2.5 mg diluted in 10 mL of NS), repeated every 3-5 min during resuscitation (follow each IV dose with a 20-mL saline flush); elevate arm for 20-30 sec after dose; higher doses (up to 0.2 mg/kg) may be used for specific indications (e.g., beta-blocker or calcium channel blocker overdose; poison/drug-induced shock)
Pediatric:
IV/IO dose: 0.01 mg/kg (1:10,000, 0.1 mL/kg) every 3-5 min during arrest; max dose: 1 mg
All ET doses: 0.1 mg/kg of 1:1000 (0.1 mL/kg) every 5 min of arrest until IV/IO access; then begin with first IV/IO dose
Continuous Infusions for Pulseless Arrest
Adult: Add 1 mg of epinephrine (1 mL of 1:1000 solution) to 500 mL of NS or D_5W; initial infusion rate of 0.1-0.5 mcg/kg/min; titrate to response
Anaphylactic Reaction or Bronchoconstriction
Adult:
Mild: 0.3-0.5 mL (1:1000) IM/subQ; repeat in 15-20 min if needed
Severe: 1 mL (1:10,000) slow IV over 5 min; IV infusion at rates of 1-4 mcg/min may prevent the need to repeat epinephrine injections frequently
Pediatric: Severe: 0.01 mg/kg (0.01 mL/kg of 1:1000) IM; max single dose: 0.3 mg; repeat as needed

SPECIAL CONSIDERATIONS

Pregnancy safety: Category C
Do not use prefilled syringes for epinephrine infusions.
Syncope has occurred following epinephrine administration to asthmatic children.
Epinephrine may increase myocardial oxygen demand.

NOTE

Complications of IV administration of epinephrine are significant and include the development of uncontrolled systolic hypertension, vomiting, seizures, dysrhythmias, and myocardial ischemia. This route should be used only in patients with a critical life-threatening condition. Intravenous administration of epinephrine rarely is performed in conscious patients. Intravenous administration is performed with extreme caution in rare circumstances and only with authorization from medical direction. *Epinephrine 1:1000 should never be given as an IV bolus.*

EPINEPHRINE RACEMIC (MICRONEFRIN)

CLASS

Sympathomimetic

DESCRIPTION

As with other forms of epinephrine, racemic epinephrine acts as a bronchodilator that stimulates $beta_2$ receptors in the lungs, resulting in relaxation of bronchial smooth muscle. This alleviates bronchospasm, increases vital capacity, and reduces airway resistance. Racemic epinephrine is also useful in treating laryngeal edema. Racemic epinephrine also inhibits the release of histamine.

ONSET AND DURATION

Onset: Within 5 min
Duration: 1-3 hr

INDICATIONS

Bronchial asthma
Treatment of bronchospasm
Croup (laryngotracheobronchitis)
Laryngeal edema

CONTRAINDICATIONS

Hypertension
Underlying cardiovascular disease
Epiglottitis

ADVERSE REACTIONS

Tachycardia
Dysrhythmias

DRUG INTERACTIONS

MAO inhibitors may potentiate the effect of epinephrine.
Beta-adrenergic antagonists may blunt the bronchodilating response.

Sympathomimetics and phosphodiesterase inhibitors may exacerbate dysrhythmia response.

HOW SUPPLIED

Metered-dose inhaler: 0.16-0.25 mg/spray
Solution: 7.5, 15, 30 mL in 1%, 2.25% solution

DOSAGE AND ADMINISTRATION

Metered-Dose Inhaler
Adult: 2-3 inhalations, repeat once in 5 min prn
Solution
Adult: Dilute 5 mL (1%) in 5 mL of saline, administer over 15 min
Pediatric: Dilute 0.25 mL (0.1%) in 2.5 mL of saline (if less than 20 kg); 0.5 mL in 2.5 mL of saline (if 20-40 kg); 0.75 mL in 2.5 mL of saline (if greater than 40 kg); administer by aerosolization

SPECIAL CONSIDERATIONS

Pregnancy safety: Category C
Racemic epinephrine may produce tachycardia and other dysrhythmias.
Monitor vital signs closely.
Excessive use may cause bronchospasm.
Rebound exacerbation of severe croup may occur following drug administration.

EPTIFIBATIDE (INTEGRILIN)

CLASS

Glycoprotein IIb/IIIa inhibitor

DESCRIPTION

Glycoprotein IIb/IIIa inhibitors inhibit the integrin GP IIb/IIIa receptor in the membrane of the platelets. As a result, they inhibit the common final pathway activation of platelet aggregation.

ONSET AND DURATION

Onset: Rapid
Duration: 30-45 min; platelet aggregation restored within 4 hr after infusion stopped

INDICATIONS

Eptifibatide (in combination with aspirin and heparin) is indicated for use in patients undergoing percutaneous coronary intervention (PCI) as well as for the treatment of unstable angina or non-STEMI myocardial infarction.

CONTRAINDICATIONS

Active internal bleeding
Bleeding disorder within the past 30 days
History of intracranial hemorrhage, neoplasm, AV malformation, aneurysm, or stroke within 30 days
Major surgical procedure or trauma within 1 month
Aortic dissection, pericarditis, and severe hypertension
Hypersensitivity to any GP IIb/IIIa inhibitor
Low platelet count

ADVERSE REACTIONS

Anaphylactoid reaction/anaphylactic shock
Bleeding
GI bleeding
Hematemesis
Hematuria
Hypotension
Intracranial bleeding
Platelet dysfunction
Retroperitoneal bleeding
Stroke
Thrombocytopenia

DRUG INTERACTIONS

Concomitant use of eptifibatide and other agents that may affect hemostasis, such as anticoagulants, other platelet inhibitors, NSAIDs, and thrombolytic agents, may be associated with an increased risk of bleeding.

HOW SUPPLIED

Solution: 0.75 mg/mL, 2.0 mg/mL

DOSAGE AND ADMINISTRATION (ADULTS)

Unstable angina and NSTEMI myocardial infarction (PCI): 180 mcg/kg IV (max: 22.6 mg) bolus over 1-2 min, followed by 2 mcg/kg/min (max: 15 mg/hr) continuous IV infusion; repeat bolus in 10 min. Decrease dose in patients with impaired renal function.

SPECIAL CONSIDERATIONS

Pregnancy safety: Category B
Bleeding risk may be increased in patients receiving eptifibatide concomitantly with heparin, other anticoagulant therapy, or thrombolytics.
Eptifibatide should not be used in patients with renal failure and is contraindicated in patients with dependency on renal dialysis.
Elderly patients may be at increased risk for bleeding while receiving eptifibatide.

ESMOLOL (BREVIBLOC)

CLASS

Beta$_1$ blocker

DESCRIPTION

Esmolol is an extremely short-acting cardioselective beta blocker. Unlike other beta$_1$-selective beta blockers (e.g., metoprolol, atenolol), esmolol is administered via continuous IV infusion. It has a short duration of action, making it useful for acute control of hypertension or certain supraventricular dysrhythmias, such as sinus tachycardia, atrial flutter and/or fibrillation in the emergency setting. Nonapproved indications include short-term control of

perioperative hypertension, management of tachydysrhythmias complicating acute MI, and minimization of acute myocardial ischemia secondary to acute MI or unstable angina.

ONSET AND DURATION

Onset: Rapid
Duration: Less than 10 min

INDICATIONS

All patients with suspected MI and unstable angina in the absence of contraindications (can reduce the incidence of VF)
Useful as an adjunctive agent with fibrinolytic therapy (may reduce nonfatal reinfarction and recurrent ischemia)
To convert to normal sinus rhythm or to slow ventricular response (or both) in supraventricular tachydysrhythmias (reentry SVT, atrial fibrillation, or atrial flutter)
To reduce myocardial ischemia in AMI patients with elevated heart rate, blood pressure, or both

CONTRAINDICATIONS

Hemodynamically unstable patients
STEMI if signs of heart failure, low cardiac output, or increased risk for cardiogenic shock are present
Relative contraindications include P-R interval >0.24 sec, second- or third-degree heart block, active asthma, reactive airway disease, severe bradycardia, SBP <100 mm Hg

ADVERSE REACTIONS

Myocardial depression
AV block
Bradycardia
Cardiac arrest
Diaphoresis
Dizziness
Headache
Hyperglycemia
Hypoglycemia
Hypotension
Nausea
Vomiting

DRUG INTERACTIONS

A potentially clinically significant interaction between esmolol and digoxin may exist because of their additive effects on the AV node.
Esmolol can potentiate the suppressive effects of diltiazem and verapamil on AV nodal conduction.
Depression of AV nodal conduction and myocardial function are possible when used in combination with adenosine, disopyramide, or other antidysrhythmics or drugs, especially in patients with preexisting left ventricular dysfunction.
Careful titration of esmolol is prudent when given with morphine.

HOW SUPPLIED

Solution: 10 mg/mL; 20 mg/mL

DOSAGE AND ADMINISTRATION

0.5 mg/kg (500 mcg/kg) over 1 minute, followed by 0.05 mg/kg (50 mcg/kg) per minute infusion; maximum: 0.3 mg/kg (300 mcg/kg) per minute.
If inadequate response after 5 minutes, may repeat 0.5 mg/kg (500 mcg/kg) bolus and then titrate infusion up to 0.2 mg/kg (200 mcg/kg) per minute. Higher doses are unlikely to be beneficial.
Has a short half-life (2 to 9 minutes).

SPECIAL CONSIDERATIONS

Pregnancy safety: Category C
Administration of esmolol can exacerbate Raynaud's disease or peripheral vascular disease.
Use with caution in patients with poorly controlled diabetes mellitus or renal disease.
Avoid extravasation of esmolol during intravenous administration. Sloughing of the skin and necrosis have been reported following infiltration and extravasation of IV esmolol infusions.

ETOMIDATE (AMIDATE)

CLASS

Nonbarbiturate hypnotic, anesthetic

DESCRIPTION

Etomidate is a short-acting drug that acts at the level of the reticular activating system to produce anesthesia. Etomidate may be administered for conscious sedation to relieve apprehension or impair memory before tracheal intubation or cardioversion.

ONSET AND DURATION

Onset: Less than 1 min
Duration: 5-10 min

INDICATIONS

Premedication for tracheal intubation or cardioversion

CONTRAINDICATIONS

Hypersensitivity to etomidate
Labor/delivery

ADVERSE REACTIONS

Nausea and vomiting
Dysrhythmias
Breathing difficulties
Hypotension
Hypertension
Involuntary muscle movement

Pain at injection site
Cortisol suppression

DRUG INTERACTIONS

Effects may be enhanced when given with other central nervous system depressants.

HOW SUPPLIED

2 mg/mL vials

DOSAGE AND ADMINISTRATION FOR RSI

Adult: 0.2-0.4 mg/kg IV over 30-60 sec; limit to 1 dose
Pediatric (>10 years of age): 0.2-0.4 mg/kg for sedation infused over 30-60 sec; max dose: 20 mg

SPECIAL CONSIDERATIONS

Pregnancy safety: Category C
Carefully monitor vital signs.
Etomidate can suppress adrenal gland production of steroid hormones, which can cause temporary gland failure.
Avoid routine use in patients suspected to have septic shock.

FENTANYL (SUBLIMAZE)

CLASS

Opioid analgesic

DESCRIPTION

Fentanyl (like other opioids) combines with receptor sites in the brain to produce potent analgesic effects. The drug often is given in combination with benzodiazepines for conscious sedation.

ONSET AND DURATION

Onset: 1-2 min (IV)
Duration: ½ to 1 hr

INDICATIONS

Pain control
Sedation for invasive airway procedures (e.g., rapid sequence induction)

CONTRAINDICATIONS

Respiratory depression
Hypotension
Head injury
Cardiac dysrhythmias
Myasthenia gravis
Hypersensitivity to opiates

ADVERSE REACTIONS

Respiratory depression
Bradycardia
Hypotension or hypertension
Nausea and vomiting
Chest wall muscle rigidity

DRUG INTERACTIONS

Effects may be increased when given with other central nervous system depressants or skeletal muscle relaxants.

HOW SUPPLIED

0.05-0.1 mg/mL ampules

DOSAGE AND ADMINISTRATION

Adult: 0.05-0.1 mg IV slow IV over 1-2 min every 1-2 hr as needed to control pain
Child: 1-2 mcg/kg; rarely used in the prehospital setting
Rapid Sequence Intubation
2-5 mcg/kg IV/IO

SPECIAL CONSIDERATIONS

Pregnancy safety: Category C
Fentanyl is a schedule II drug with the potential for abuse.
Fentanyl should be used (if at all) with caution in elderly patients and in those with severe respiratory disorders, seizure disorders, cardiac disorders, or pregnancy.
Naloxone or nalmefene should be available to reverse respiratory depression.

FLUMAZENIL (ROMAZICON)

CLASS

Benzodiazepine receptor antagonist, antidote

DESCRIPTION

Flumazenil antagonizes the actions of benzodiazepines in the central nervous system. It has been shown to reverse sedation, impairment of recall, and psychomotor impairment produced by benzodiazepines. Flumazenil is not, however, as effective in reversing hypoventilation. Flumazenil does not antagonize central nervous system effects of ethanol, barbiturates, or opioids.

ONSET AND DURATION

Onset: 1-2 min
Duration: Related to plasma concentration of benzodiazepine

INDICATIONS

Reversal of respiratory depression and sedation from pure benzodiazepine overdose

CONTRAINDICATIONS

Hypersensitivity to flumazenil or to benzodiazepines
Tricyclic antidepressant overdose
Chronic benzodiazepine users or alcoholics
Cocaine or other stimulant intoxication
Known seizure disorder (relative)

ADVERSE REACTIONS

Nausea and vomiting
Dizziness
Headache
Agitation
Injection site pain
Cutaneous vasodilation
Abnormal vision
Seizures

DRUG INTERACTIONS

Toxic effects of mixed drug overdose (especially tricyclic antidepressants) may emerge with the reversal of the benzodiazepine effects.

HOW SUPPLIED

5- and 10-mL vials (0.1 mg/mL)

DOSAGE AND ADMINISTRATION

For Suspected Benzodiazepine Overdose
Adult:
First dose: 0.2 mg IV over 15 sec
Second dose: 0.3 mg IV over 30 sec
Third dose: 0.5 mg over 30 sec at 1-min intervals until adequate response or max dose of 3 mg is given
Pediatric: Not recommended

SPECIAL CONSIDERATIONS

Pregnancy safety: Category C
To minimize the likelihood of injection site pain, administer through an IV infusion established in a large vein.
Be prepared to manage seizures in patients who are physically dependent on benzodiazepines to control seizures or who have ingested large doses of other drugs.
Flumazenil may precipitate withdrawal syndromes in patients who are dependent on benzodiazepines.
Patients should be monitored for possible resedation, respiratory depression, or other residual benzodiazepine effects.
Be prepared to establish and assist ventilation.

FUROSEMIDE (LASIX)

CLASS

Loop diuretic

DESCRIPTION

Furosemide is a potent diuretic that inhibits the reabsorption of sodium and chloride in the proximal tubule and loop of Henle. Intravenous doses also can reduce cardiac preload by increasing venous capacitance.

ONSET AND DURATION

Onset: (IV) Diuretic effects within 15-20 min; vascular effects within 5 min
Duration: 2 hr

INDICATIONS

Acute pulmonary edema in patients with a SBP >90-100 mm Hg (without signs and symptoms of shock)
Hypertensive emergencies
Hyperkalemia

CONTRAINDICATIONS

Anuria (though loop diuretics can be used in patients with reduced creatinine clearance)
Hypersensitivity
Hypovolemia/dehydration
Known hypersensitivity to sulfonamides (caution)
Severe electrolyte depletion (hypokalemia)

ADVERSE REACTIONS

Hypotension
Electrocardiogram changes associated with electrolyte disturbances
Dry mouth
Hypochloremia
Hypokalemia
Hyponatremia
Hypocalcemia
Hyperglycemia
Hearing loss can occur rarely after too rapid infusion of large doses especially in patients with renal impairment.

DRUG INTERACTIONS

Digitalis toxicity may be potentiated because of potassium depletion, which can result from furosemide administration.
Furosemide increases ototoxic potential of aminoglycoside antibiotics.
Lithium toxicity may be potentiated because of sodium depletion.
Furosemide may potentiate therapeutic effect of other antihypertensive drugs.

HOW SUPPLIED

Parenteral: 10 mg/mL in 2-, 4-, 8-mL ampule, 10 mg/mL in 10-mL vial

DOSAGE AND ADMINISTRATION

IV: 0.5-1 mg/kg over 1-2 min; if no response, double dose to 2 mg/kg given slowly over 1-2 min; for new-onset pulmonary edema with hypovolemia, give <0.5 mg/kg
Pediatric: 1 mg/kg/dose (max total dose: 6 mg/kg)
Hyperkalemia (adult): 40-80 mg IV

SPECIAL CONSIDERATIONS

Pregnancy safety: Category C
Furosemide has been known to cause fetal abnormalities.
Furosemide should be protected from light and stored at room temperature; do not use if solution is discolored or yellow.

GLUCAGON

CLASS

Pancreatic hormone, antihypoglycemic agent

DESCRIPTION

Glucagon is a protein secreted by the alpha cells of the pancreas. When released, glucagon results in blood glucose elevation by increasing the breakdown of glycogen to glucose (glycogenolysis) and stimulating glucose synthesis (gluconeogenesis). The drug is only effective in treating hypoglycemia if liver glycogen is available and therefore may be ineffective in chronic states of hypoglycemia, starvation, and adrenal insufficiency. In addition, glucagon exerts positive inotropic action on the heart and decreases renal vascular resistance. For this reason, glucagon also is used in managing patients with beta-blocker and calcium channel blocker cardiotoxicity who do not respond to saline infusions or other conventional therapy.

ONSET AND DURATION

Onset: Within 1 min
Duration: 60-90 min

INDICATIONS

Hypoglycemia
Calcium channel blocker or beta-blocker toxicity

CONTRAINDICATIONS

Hypersensitivity (allergy to proteins)

ADVERSE REACTIONS

Tachycardia
Hypotension
Nausea and vomiting
Urticaria

DRUG INTERACTIONS

Effect of anticoagulants may be increased if given with glucagon.
Do not mix with saline.

HOW SUPPLIED

Glucagon must be reconstituted (with provided diluent) before administration. Dilute 1 unit (1 mg) of white powder in 1 mL of diluting solution (1 mg/mL).

DOSAGE AND ADMINISTRATION

Hypoglycemia
Adult: 0.5-1 mg IM; may repeat in 7-10 min
Pediatric: For >20 kg, 0.5-1 mg IM
Calcium Channel Blocker or Beta-Blocker Toxicity
Adult: 3-10 mg slow IV over 3-5 min, followed by infusion at 3-5 mg/hr
Pediatric: Safety and efficacy have not been established.

SPECIAL CONSIDERATIONS

Pregnancy safety: Category B
Glucagon should not be considered a first-line choice for hypoglycemia.
May cause vomiting and hyperglycemia.
Intravenous glucose will need to be administered if the patient does not respond to a second dose of glucagon.
Do not use the provided diluent to mix continuous infusions.

HALOPERIDOL LACTATE (HALDOL)

CLASS

Antipsychotic/neuroleptic

DESCRIPTION

Haloperidol has pharmacological properties similar to those of the phenothiazines. The drug is thought to block dopamine (type 2) receptors in the brain, altering mood and behavior. In emergency care, haloperidol usually is administered IM.

ONSET AND DURATION

Onset: (IM) 30-60 min
Duration: 12-24 hr

INDICATIONS

Acute psychotic episodes
Emergency sedation of severely agitated or delirious patients

CONTRAINDICATIONS

Central nervous system depression
Coma
Hypersensitivity
Pregnancy
Severe liver or cardiac disease

ADVERSE REACTIONS

Dose-related extrapyramidal reactions:
Pseudoparkinsonism
Akathisia
Dystonias
Hypotension
Orthostatic hypotension
Nausea, vomiting
Allergic reactions
Blurred vision
Drowsiness

DRUG INTERACTIONS

Other central nervous system depressants may potentiate effects.
Haloperidol may inhibit vasoconstrictor effects of epinephrine.

HOW SUPPLIED

5 mg/mL

DOSAGE AND ADMINISTRATION

Adult: 2-5 mg IM every 4-8 hr as needed
Pediatric: Safety not established

SPECIAL CONSIDERATIONS

Pregnancy safety: Category C

HEPARIN

Low Molecular Weight Heparin (Enoxaparin)

CLASS

Anticoagulant

DESCRIPTION

Heparin is available as Low Molecular Weight Heparin (LMWH [Enoxaparin]) and Unfractionated Heparin (UFH). Both inhibit the clotting cascade by activating specific plasma proteins. Natural heparin (heparin sodium) consists of molecular chains of varying lengths or *molecular weights*. LMWHs consist of only short chains of molecular weight and produce a more predictable coagulation response than UFH.[2] The use of LMWH has been approved for both the prevention and treatment of acute deep vein thrombosis, acute pulmonary embolism, and for the treatment of acute coronary syndromes.

ONSET AND DURATION

Onset: (IV) Immediate
(SQ) 20-60 min
Duration: 4-8 hr

INDICATIONS

ACS,
Acute deep vein thrombosis
Acute pulmonary embolism

CONTRAINDICATIONS

Same as for fibrinolytic therapy
Renal insufficiency
Active bleeding or low platelet count
Hypersensitivity to heparin or pork products
Recent intracranial, intraspinal, or eye surgery
Severe hypertension
Heparin-induced thrombocytopenia

ADVERSE REACTIONS

Allergic reaction (chills, fever, back pain)
Thrombocytopenia
Hemorrhage
Bruising
Rash

DRUG INTERACTIONS

None noted
Salicylates, ibuprofen, dipyridamole, and hydroxychloroquine may increase risk of bleeding.

HOW SUPPLIED

Concentrations range from 30 mg to 150 mg in various mL of solution for SQ or IV administration

DOSAGE AND ADMINISTRATION

STEMI Protocol
- Age <75 years: initial bolus 30 mg IV with second bolus 15 min later of 1 mg/kg SQ (max 100 mg dose for first 2 doses).
- Age ≥75 years: Eliminate initial IV bolus; give 0.75 mg/kg SQ every 12 hours (max 75 mg dose for first 2 doses).

Should use UFH if early cardiac catheterization (within 12 hours) is planned.
UA/NSTEMI Protocol
Loading dose: 30 mg IV bolus; maintenance dose 1 mg/kg SQ every 12 hours.
Deep Vein Thrombosis (DVT) or Pulmonary Embolism Protocol
Adults: 1 mg/kg SQ every 12 hours or 1.5 mg/kg SC every 24 hours.

SPECIAL CONSIDERATIONS

Pregnancy safety: Category B
The platelet count should be monitored in patients receiving enoxaparin.
Always follow institutional protocol regarding heparin administration.
Multiple-dose vials of enoxaparin contain benzyl alcohol (1.5%) as a preservative and should be avoided in patients with benzyl alcohol hypersensitivity.
Do not administer IM.
Enoxaparin cannot be used interchangeably (unit for unit) with heparin sodium or other low molecular weight heparins.
Do not mix with other products or infusion fluids.

HEPARIN SODIUM

Unfractionated (UFH)

CLASS

Anticoagulant

DESCRIPTION

Heparin inhibits the clotting cascade by activating specific plasma proteins. The drug is used in the prevention and treatment of all types of thromboses and emboli, disseminated intravascular coagulation, arterial occlusion, and thrombophlebitis and is used prophylactically to prevent clotting before surgery. Heparin is considered part of the antithrombotic package (along with aspirin and fibrinolytic agents) administered to patients

with STEMI, UA/NSTEMI, and acute coronary syndromes.

ONSET AND DURATION

Onset: (IV) Immediate
(SQ) 20-60 min
Duration: 4-8 hr

INDICATIONS

Acute myocardial infarction
UA/NSTEMI
STEMI
Prophylaxis and treatment of thromboembolic disorders (e.g., pulmonary emboli and deep venous thrombosis)

CONTRAINDICATIONS

Same as for fibrinolytic therapy
Hypersensitivity
Active bleeding
Recent intracranial, intraspinal, or eye surgery
Severe hypertension
Bleeding tendencies
Severe thrombocytopenia

ADVERSE REACTIONS

Allergic reaction (chills, fever, back pain)
Thrombocytopenia
Hemorrhage
Bruising
Rash

DRUG INTERACTIONS

Salicylates, ibuprofen, dipyridamole, and hydroxychloroquine may increase risk of bleeding.

HOW SUPPLIED

Concentrations range from 1000 to 40 000 units/mL

DOSAGE AND ADMINISTRATION

IV Infusion- STEMI and UA/NSTEMI
Initial bolus of 60 units/kg (max bolus: 4000 units); continue 12 units/kg/hr, round to the nearest 50 units (max initial rate: 1000 units/hr).

SPECIAL CONSIDERATIONS

Pregnancy safety: Category C
Dosing should be guided by laboratory analysis of platelet count and partial thromboplastin time. Always follow institutional protocol regarding heparin administration.

HYDROMORPHONE (DILAUDID)

CLASS

Analgesic; opiate agonist

DESCRIPTION

Hydromorphone is a semisynthetic analog of morphine used to relieve moderate to severe pain in cancer, surgery, trauma, burn, and cardiac patients. The drug works at opioid receptors to produce analgesia and euphoria. It may also produce respiratory depression, miosis, decreased gastrointestinal motility, and physical dependence. Hydromorphone is a schedule II controlled substance.

ONSET AND DURATION

Onset (IV/IM): Within 15 min (dose related)
Duration: 4-5 hr in nondependent patients

INDICATIONS

Moderate to severe pain
Analgesia
Preoperative medication

CONTRAINDICATIONS

Asthma
GI obstruction
Hypersensitivity to narcotics
Ileus
Respiratory depression
Status asthmaticus

ADVERSE REACTIONS

Respiratory depression
Nausea and vomiting
Euphoria
Delirium
Agitation
Hallucination
Seizures
Headache
Hypotension
Visual disturbances
Coma
Facial flushing
Circulatory collapse
Dysrhythmias
Allergic reaction
Drowsiness
Rash

DRUG INTERACTIONS

Respiratory depression, hypotension, or sedation may be potentiated by central nervous system depressants.
Therapeutic doses of hydromorphone have caused additive CNS or respiratory depression and hypotension in patients taking MAO inhibitors.

HOW SUPPLIED

Solution for injection: 1 mg/mL, 2 mg/mL, 4 mg/mL

DOSAGE AND ADMINISTRATION

Adult: 1-2 mg subQ/IM or slow IV every 6 hr; titrate to pain relief
Pediatric (>50 kg): 1 mg IV/subQ every 4 hr; pediatric (<50 kg or >6 months of age): 0.015-0.02 mg/kg IV/subQ every 2-4 hr; titrate to pain relief

SPECIAL CONSIDERATIONS

Pregnancy safety: Category C
High potential for abuse
Use with extreme caution in patients with head trauma, increased intracranial pressure (ICP), or a preexisting seizure disorder.
Use with caution in patients with cardiac dysrhythmias, hypotension, circulatory shock, or hypovolemia.
Elderly patients may be more susceptible to adverse reactions.
Can induce vasovagal syncope or orthostatic hypotension.
Naloxone should be readily available.

HYDROXOCOBALAMIN (CYANOKIT)

CLASS

Vitamin; antidote

DESCRIPTION

Hydroxocobalamin is a parenteral preparation of vitamin B_{12}; specifically, it is the hydroxylated active form of vitamin B_{12}. Hydroxocobalamin is used to treat known or suspected cyanide toxicity.

ONSET AND DURATION

Onset: Rapid
Duration: Greater than 24 hr

INDICATIONS

Known or suspected cyanide poisoning

CONTRAINDICATIONS

Known hydroxocobalamin hypersensitivity

ADVERSE REACTIONS

Allergic reaction/anaphylaxis
Elevated blood pressure
Headache
Hypertension
Injection site reaction
Nausea
Photophobia
Red-colored urine

DRUG INTERACTIONS

None

HOW SUPPLIED

Powder for injection: 5 g
Solution: 1000 mcg/mL

DOSAGE AND ADMINISTRATION

Adults: Initially, 5 g (two 2.5-g vials) IV infused over 15 min (approximately 15 mL/min or 7.5 min per vial). A second 5-g dose infused over 15 min to 2 hr (depending on patient status), for a total of 10 g, may be administered based on clinical response and severity of cyanide poisoning
Children: Doses of 70 mg/kg IV have been used; not FDA approved

SPECIAL CONSIDERATIONS

Pregnancy safety: Category C
Before administration of the antidote, a blood sample should be taken to determine the cyanide concentration.
Treatment of cyanide poisoning includes supportive therapy, such as cardiovascular support, airway/ventilation management, control of seizure activity, and hydration in addition to the use of hydroxocobalamin.
Solution is bright red.

IBUTILIDE (CORVERT)

CLASS

Short-acting Class III antidysrhythmic

DESCRIPTION

Ibutilide prolongs the action potential duration and increases the refractory period of cardiac tissue. Ibutilide is recommended to convert acute supraventricular dysrhythmias, including atrial flutter and atrial fibrillation, when their duration is 48 hours or less. The drug may also be used as an adjunct to electrical cardioversion.

ONSET AND DURATION

Onset: ½ to 1½ hr
Duration: 10-12 hr

INDICATIONS

Supraventricular dysrhythmias
Conversion of atrial fibrillation and atrial flutter of brief duration

CONTRAINDICATIONS

History of heart failure or ventricular tachycardia
Patients with QTc >400 ms
Sensitivity to ibutilide

ADVERSE REACTIONS

Ventricular dysrhythmias, including polymorphic VT, torsades
Bradycardia
Hypotension and hypertension
Headache

DRUG INTERACTIONS

Avoid concurrent administration of ibutilide with other antidysrhythmics that prolong the refractory period

(e.g., amiodarone) or drugs that induce Q-T interval prolongation (e.g., procainamide).

HOW SUPPLIED

1 mg in 10-mL ampules

DOSAGE AND ADMINISTRATION

Adult (60 kg or more): 1 mg (10 mL) diluted or undiluted IV over 10 min. A second dose may be administered at the same rate 10 min later. The initial dose for adults who weigh less than 60 kg is 0.01 mg/kg IV.
Pediatric: Not recommended

SPECIAL CONSIDERATIONS

Pregnancy safety: Category C
Ibutilide must be given slowly IV over 10 min. This may make it impractical for use in emergent situations.
Ventricular dysrhythmias develop in 2% to 5% of patients who are given ibutilide; continuous electrocardiogram monitoring is essential.
Use with caution in patients with impaired left ventricular function.

INSULIN (REGULAR, NPH, AND OTHERS)

CLASS

Antidiabetic agent

DESCRIPTION

Insulin is secreted by the beta cells (islets of Langerhans) of the pancreas and is required for proper glucose utilization by the body. If insulin secretion is diminished (as in diabetes mellitus), supplemental insulin must be obtained by injection. Insulin preparations are classified as *short-acting* (regular) and *intermediate-acting* (NPH). Insulin seldom is administered in the prehospital setting, even when ketoacidosis is present. (Large amounts of normal saline solution are considered the first-line treatment.) Insulin may be required for long transport times.

ONSET AND DURATION

Onset: ½ to 1 hr (short-acting); 1 to 1½ hr (intermediate-acting); 4-6 hr (long-acting)
Duration: 6-8 hr (short-acting); 18-24 hr (intermediate-acting)

INDICATIONS

Type 1 diabetes mellitus
Type 2 diabetes mellitus if oral hypoglycemic agents do not control blood glucose adequately
Diabetic ketoacidosis
Nonketotic hyperosmolar coma
Insulin and 50% dextrose solution are given together to lower potassium levels in hyperkalemia.

CONTRAINDICATIONS

Hypoglycemia

ADVERSE REACTIONS

Hypoglycemia
Fatigue
Weakness
Confusion
Headache
Tachycardia
Rapid, shallow breathing
Nausea
Diaphoresis
Allergic reaction

DRUG INTERACTIONS

Corticosteroids, dobutamine, epinephrine, and thiazide diuretics may antagonize (decrease) the hypoglycemic effects of insulin.
Alcohol, beta-adrenergic blockers, MAO inhibitors, and salicylates may potentiate (increase) the hypoglycemic effects of insulin.

HOW SUPPLIED

100 units/mL in 10-mL vials

DOSAGE AND ADMINISTRATION

Insulin may be administered subQ or IM. Regular insulin can be given IV, and dosage is governed by the clinical presentation of the patient. A standard dose of insulin administration is as follows:
Adult: 10-25 units of regular insulin IV, followed by an infusion of 0.1 unit/kg/hr
Pediatric: 0.1-0.2 unit/kg/hr IM
Infusion: 100 units of regular insulin mixed in 100 mL of NS (1 unit/mL), infused at a rate of 0.1-0.2 unit/kg/hr (use infusion pump)

SPECIAL CONSIDERATIONS

Pregnancy safety: Category B
Insulin is the drug of choice for control of diabetes in pregnancy.
Insulin injected into the abdominal wall is absorbed most rapidly, insulin in the arm is absorbed more slowly, and insulin is absorbed slowest when injected into the thigh.

IPRATROPIUM (ATROVENT)

CLASS

Anticholinergic, bronchodilator

DESCRIPTION

Ipratropium inhibits interaction of acetylcholine at receptor sites on bronchial smooth muscle, resulting in decreased levels of cyclic guanosine monophosphate and bronchodilation.

ONSET AND DURATION

Onset: 5-15 min
Duration: 4-6 hr

INDICATIONS

Persistent bronchospasm
Chronic obstructive pulmonary disease exacerbation

CONTRAINDICATIONS

Hypersensitivity to ipratropium, atropine, alkaloid, soybean protein, peanuts

ADVERSE REACTIONS

Nausea and vomiting
Cramps
Coughing
Worsening of symptoms
Headache
Tachycardia
Dry mouth
Blurred vision
Anxiety

DRUG INTERACTIONS

None reported

HOW SUPPLIED

Aerosol 17-18—nebulizer
18 mcg—MDI

DOSAGE AND ADMINISTRATION

NOTE: When used in combination with beta agonists (e.g., albuterol), the beta agonist is always administered first with a 5-min wait before administering ipratropium.
Adult: 1-2 inhalations
Pediatric: 250-500 mcg (by nebulizer or MDI) every 20 min times 3 doses

SPECIAL CONSIDERATIONS

Pregnancy safety: Category B
Shake well before use.
Use with caution in patients with urinary retention.

ISOPROTERENOL (ISUPREL)

CLASS

Sympathomimetic

DESCRIPTION

Isoproterenol is a synthetic catecholamine that stimulates both $beta_1$- and $beta_2$-adrenergic receptors (no alpha-receptor stimulation). The drug affects the heart by increasing inotropic and chronotropic activity. In addition, isoproterenol causes arterial and bronchial dilation and sometimes is administered via aerosolization as a bronchodilator to treat bronchial asthma and bronchospasm. (Because of the undesirable $beta_1$ cardiac effects, the use of this drug as a bronchodilator is uncommon in the prehospital setting.) Isoproterenol should be used cautiously as a temporizing measure if an external pacer is not available for symptomatic bradycardia.

ONSET AND DURATION

Onset: 1-5 min
Duration: 15-30 min

INDICATIONS

Hemodynamically significant bradycardias secondary to beta-blocker overdose
Management of refractory torsades de pointes, unresponsive to magnesium sulfate
Temporary control of bradycardia in heart transplant patients, unresponsive to atropine

CONTRAINDICATIONS

Ventricular tachycardia
Ventricular fibrillation
Hypotension (relative)
Pulseless idioventricular rhythm
Ischemic heart disease/angina (relative)
Cardiac arrest
Acetylcholinesterase-induced bradycardias
Poison/drug-induced shock (other than beta-blocker poisoning)

ADVERSE REACTIONS

Dysrhythmias
Hypotension
Precipitation of angina pectoris
Facial flushing
Restlessness
Dry throat
Discoloration of saliva (pinkish red)

DRUG INTERACTIONS

MAO inhibitors potentiate the effects of catecholamines.
Beta-adrenergic antagonists may blunt inotropic response.
Sympathomimetics and phosphodiesterase inhibitors may exacerbate dysrhythmia response.
Do not give with epinephrine; can cause VF or VT.

HOW SUPPLIED

5-mL (0.2 mg/mL) vial; 0.02 mg/mL in 1- and 10-mL vials

DOSAGE AND ADMINISTRATION

Adult: Dilute 1 mg in 250 mL of D_5W (4 mcg/mL); infuse at 2-10 mcg/min or until the desired heart rate is obtained; in torsades de pointes, titrate to increase heart rate until ventricular tachycardia is suppressed
Pediatric: Not recommended

SPECIAL CONSIDERATIONS

Pregnancy safety: Category C
Isoproterenol increases myocardial oxygen demand and can induce serious dysrhythmias (including ventricular tachycardia and ventricular fibrillation).
Administer via infusion pump to ensure precise flow rates.
Isoproterenol may exacerbate tachydysrhythmias caused by digitalis toxicity or hypokalemia.
Newer inotropic agents have replaced isoproterenol in most clinical settings.
If electronic pacing is available, it should be used instead of isoproterenol or as soon as possible after drug administration has been initiated.

KETAMINE (KETALAR)

CLASS

Nonbarbiturate anesthetic

DESCRIPTION

Ketamine acts on the limbic system and cortex to block afferent transmission of impulses associated with pain perception. It produces short-acting amnesia without muscular relaxation. Ketamine is a derivative of a drug of abuse, phencyclidine.

ONSET AND DURATION

Onset: Within 30 sec
Duration: 5-10 min

INDICATIONS

Pain control
As an adjunct to nitrous oxide

CONTRAINDICATIONS

Stroke
Increased intracranial pressure
Severe hypertension
Cardiac decompensation
Hypersensitivity to ketamine

ADVERSE REACTIONS

Hypertension
Increased heart rate
Hallucinations, delusions, explicit dreams
Less common side effects include hypotension, bradycardia, and respiratory depression

DRUG INTERACTIONS

No significant drug interactions have been reported.

HOW SUPPLIED

10, 50, and 100 mg/mL vials

DOSAGE AND ADMINISTRATION

Adult: 1-2 mg/kg IV over 1 min or 4-5 mg/kg IM
Child (>2 years of age): 1-2 mg/kg IV over 1 min or 3-5 mg/kg IM
Rapid Sequence Intubation
1-2 mg/kg IV/IO

SPECIAL CONSIDERATIONS

Pregnancy safety: Category C
Ketamine may increase blood pressure, muscle tone, and heart rate.
As with any anesthetic, the dosage needs to be assessed carefully and individualized.
Keep patient in a quiet environment (if possible).

KETOROLAC TROMETHAMINE (TORADOL)

CLASS

Nonsteroidal antiinflammatory

DESCRIPTION

Ketorolac tromethamine is an antiinflammatory drug that also exhibits peripherally acting nonnarcotic analgesic activity by inhibiting prostaglandin synthesis.

ONSET AND DURATION

Onset: Within 10 min
Duration: 6-8 hr

INDICATIONS

Short-term management (less than 5 days) of moderate to severe pain

CONTRAINDICATIONS

Hypersensitivity to the drug
Patients with allergies to aspirin or other nonsteroidal antiinflammatory drugs
Bleeding disorders
Renal failure
Active peptic ulcer disease

ADVERSE REACTIONS

Anaphylaxis from hypersensitivity
Edema
Sedation
Bleeding disorders
Rash
Nausea
Headache

DRUG INTERACTIONS

Ketorolac may increase bleeding time when administered to patients taking anticoagulants.
Effects of lithium and methotrexate may be increased.

HOW SUPPLIED

15 or 30 mg in 1 mL
60 mg in 2 mL

DOSAGE AND ADMINISTRATION

Adult:
- IM: 1 dose of 60 mg (for patients <65 years of age); 1 dose of 30 mg for patients >65 years of age, have renal impairment, and/or weigh less than 50 kg
- IV: 30 mg over 1 min (for patients <65 years of age or weigh less than 50 kg); one-half dose (15 mg) for patients >65 years of age, have renal impairment, and/or weigh less than 50 kg

Pediatric: Not recommended

SPECIAL CONSIDERATIONS

Pregnancy safety: Category C
Solution is clear and slightly yellow.
Use with caution and reduce dose when administering to elderly patients.

LABETALOL (TRANDATE)

CLASS

Alpha- and beta-adrenergic blocker

DESCRIPTION

Labetalol is a competitive alpha$_1$-receptor blocker and a nonselective beta-receptor blocker that is used for lowering blood pressure in hypertensive crisis. Labetalol is a more potent beta blocker than alpha blocker. Blood pressure is reduced without reflex tachycardia, and total peripheral resistance is decreased, helping maintain cardiac output. In emergency care, labetalol is administered IV.

ONSET AND DURATION

Onset: Within 5 min
Duration: 3-6 hr

INDICATIONS

Hypertensive emergencies
All patients with suspected MI and unstable angina in the absence of contraindications (can reduce the incidence of VF)
Useful as an adjunctive agent with fibrinolytic therapy (may reduce nonfatal reinfarction and recurrent ischemia)
To convert to normal sinus rhythm or to slow ventricular response (or both) in supraventricular tachydysrhythmias (reentry SVT, atrial fibrillation, or atrial flutter)
To reduce myocardial ischemia in AMI patients with elevated heart rate, blood pressure, or both

CONTRAINDICATIONS

Hemodynamically unstable patients
STEMI if signs of heart failure, low cardiac output, or increased risk for cardiogenic shock are present
Relative contraindications include P-R interval >0.24 sec, second- or third-degree heart block, active asthma, reactive airway disease, severe bradycardia, SBP <100 mm Hg

ADVERSE REACTIONS

Headache
Dizziness
Edema
Fatigue
Vertigo
Ventricular dysrhythmias
Dyspnea
Allergic reaction
Facial flushing
Diaphoresis
Dose-related orthostatic hypotension (most common)
Bradycardia
Nausea and vomiting
Tinnitus

DRUG INTERACTIONS

Bronchodilator effects of beta-adrenergic agonists may be blunted by labetalol.
Nitroglycerin may augment hypotensive effects.

HOW SUPPLIED

5 mg/mL in 4-, 8-, 20-, and 40-mL vials

DOSAGE AND ADMINISTRATION

Adult: 10 mg IV over 1-2 min. May repeat or double labetalol every 10 min to a max dose of 150 mg. Alternative dosing: Give initial dose as a bolus, and then begin infusion at 2-8 mg/min
Infusion: Mix 200 mg in 250 mL of D_5W (0.8 mg/mL); infuse at a rate of 2-8 mg/min, titrated to supine blood pressure
Pediatric: Safety has not been established; initiate cautiously with careful dosage adjustments and blood pressure monitoring

SPECIAL CONSIDERATIONS

Pregnancy safety: Category C
Blood pressure, pulse rate, and electrocardiogram should be monitored continuously.
Observe for signs of congestive heart failure, bradycardia, and bronchospasm.
Labetalol should be administered only with the patient in a supine position.

LEVALBUTEROL (XOPENEX)

CLASS

Sympathomimetic, bronchodilator, beta$_2$ agonist

DESCRIPTION

Levalbuterol is a relatively selective beta$_2$-adrenergic receptor agonist. It acts as a functional antagonist to relax the smooth muscles of all airways, from the trachea to the terminal bronchioles.

ONSET AND DURATION

Onset: 5-15 min after inhalation
Duration: 3-4 hr after inhalation

INDICATIONS

Treatment or prevention of bronchospasm in patients over 6 years of age with reversible, obstructive airway disease

CONTRAINDICATIONS

Prior hypersensitivity to levalbuterol or racemic albuterol
Cardiac dysrhythmias associated with tachycardia

ADVERSE REACTIONS

Usually dose related
Restlessness, apprehension, tremor
Chills, body pain, chest pain
Eye itch
Hypertension, hypotension, syncope
Palpitation, tachycardia
Dysrhythmias

DRUG INTERACTIONS

Other sympathomimetics may exacerbate adverse cardiovascular effects.
Antidepressants may potentiate effects on the vasculature (vasodilation).
Beta blockers may antagonize levalbuterol.
Levalbuterol may potentiate diuretic-induced hypokalemia.

HOW SUPPLIED

Solution for aerosolization: 3-mL unit dose (0.31, 0.63, 1.25 mg)
Solution packaged in color-coded foil pouches

DOSAGE AND ADMINISTRATION

Bronchospasm
Pediatric: 6-11 years old: 0.31 mg by nebulization q 6-8 hr. Dose not to exceed 0.63 mg every 6-8 hr
Adult: 12 or older: 0.63-1.25 mg by nebulization q 6-8 hr
NOTE: In settings of acute asthma, 1.25 mg of levalbuterol should be administered every 20 min for a total of 3 doses.

SPECIAL CONSIDERATIONS

Pregnancy safety: Category C
Levalbuterol should not be given to children younger than 6 years of age.
Levalbuterol may precipitate angina pectoris and dysrhythmias.
Levalbuterol is sometimes preferred over albuterol for patients with preexisting tachycardia.
Levalbuterol should be used with caution (if at all) in patients taking beta blockers, diuretics, digoxin, monamine oxidase inhibitors, or tricyclic antidepressants.

LIDOCAINE (XYLOCAINE)

CLASS

Antidysrhythmic (Class IB), local anesthetic

DESCRIPTION

Lidocaine decreases phase 4 diastolic depolarization (which decreases automaticity) and has been shown to be effective in suppressing premature ventricular complexes. In addition, lidocaine is used as an alternative to amiodarone to treat cardiac arrest from VT or VF. Lidocaine also raises the ventricular fibrillation threshold.

ONSET AND DURATION

Onset: 30-90 sec
Duration: 10-20 min

INDICATIONS

Cardiac arrest from ventricular tachycardia or ventricular fibrillation
Stable monomorphic VT with preserved ventricular function
Stable polymorphic VT with normal baseline Q-T interval and preserved LV function after correction of ischemia and electrolyte balance
Stable polymorphic VT with baseline-prolonged Q-T interval if torsades is suspected
Wide-complex tachycardia of uncertain origin
Significant ventricular ectopy in the setting of myocardial ischemia/infarction

CONTRAINDICATIONS

Prophylactic use in AMI
Hypersensitivity
Stokes-Adams syndrome
Second- or third-degree heart block in the absence of an artificial pacemaker

ADVERSE REACTIONS

Light-headedness
Confusion
Blurred vision
Hypotension
Bradycardia
Cardiovascular collapse
Bradycardia
Altered level of consciousness, irritability, muscle twitching, seizures with high doses
Headache
Seizures

DRUG INTERACTIONS

Metabolic clearance of lidocaine may be decreased in patients taking beta-adrenergic blockers or in patients with decreased cardiac output or liver dysfunction.
Apnea induced with succinylcholine may be prolonged with large doses of lidocaine.
Cardiac depression may occur if lidocaine is given concomitantly with IV phenytoin.
Additive neurological effects may occur with procainamide and tocainide.

HOW SUPPLIED

Prefilled syringes: 100 mg in 5 mL of solution; 1- and 2-g additive syringes
Ampules: 100 mg in 5 mL of solution; 1- and 2-g vials in 30 mL of solution; 5 mL containing 100 mg/mL

DOSAGE AND ADMINISTRATION

Cardiac Arrest From Ventricular Tachycardia/Ventricular Fibrillation
Adult: 1-1.5 mg/kg IV/IO bolus or endotracheal tube (at 2-2.5 times the IV dose); for refractory VF, may give additional 0.5-0.75 mg/kg IV push; repeat in 5-10 min; max 3 doses or total of 3 mg/kg
Pediatric: 1 mg/kg IV/IO loading dose; ET dose: 2-3 mg/kg
Perfusing Dysrhythmia (Stable VT; Wide-Complex Tachycardia of Uncertain Type; Significant Ectopy)
Adult: Doses may range from 0.5 to 0.75 mg/kg (up to 1-1.5 mg/kg may be used). Repeat 0.5-0.75 mg/kg every 5-10 min; max total dose 3 mg/kg
Pediatric: 1 mg/kg IV/IO. ET dose is 2-3 mg/kg
Maintenance Infusion After Resuscitation From Cardiac Arrest From Ventricular Tachycardia/Ventricular Fibrillation
Adult: 1-4 mg/min (30-50 mcg/kg/min); reduce maintenance dose (not loading dose) in presence of impaired liver function or LV dysfunction
Pediatric: 20-50 mcg/kg/min IV/IO; repeat bolus dose if infusion initiated >15 min after initial bolus therapy
Pediatric: Initial loading dose of 1 mg/kg IV/IO, followed by infusion of 20-50 mcg/kg/min
Rapid Sequence Intubation
1-2 mg/kg IV/IO (max 100 mg)

SPECIAL CONSIDERATIONS

Pregnancy safety: Category B
A 75-100 mg bolus will maintain adequate blood levels for only 20 min (in absence of shock).
If bradycardia occurs along with premature ventricular contractions, always treat the bradycardia first with atropine.
Discontinue infusion immediately if signs of toxicity develop.
Exceedingly high doses of lidocaine can result in coma or death.
Decrease dose in the elderly.
Avoid lidocaine for reperfusion dysrhythmias following fibrinolytic therapy.
Use extreme caution in patients with hepatic disease, heart failure, marked hypoxia, severe respiratory depression, hypovolemia or shock, incomplete heart block, or bradycardia and atrial fibrillation.

LORAZEPAM (ATIVAN)

CLASS

Benzodiazepine

DESCRIPTION

Lorazepam is a benzodiazepine with antianxiety and anticonvulsant effects. When given by injection, it appears to suppress the propagation of seizure activity produced by foci in the cortex, thalamus, and limbic areas.

ONSET AND DURATION

Onset: 5 min (IV)
Duration: 6-8 hr

INDICATIONS

Agitation requiring sedation
Initial control of status epilepticus or severe recurrent seizures (investigational)

CONTRAINDICATIONS

Hypersensitivity to the drug
Substance abuse (relative)
Coma (unless seizing)
Severe hypotension
Shock
Preexisting central nervous system depression

ADVERSE REACTIONS

Respiratory depression
Tachycardia/bradycardia
Hypotension
Sedation
Ataxia
Psychomotor impairment
Confusion
Blurred vision

DRUG INTERACTIONS

Lorazepam may precipitate central nervous system depression and psychomotor impairment when the patient is taking central nervous system depressant medications.

HOW SUPPLIED

2 and 4 mg/mL concentrations in 1-mL vials

DOSAGE AND ADMINISTRATION

Before IV administration, lorazepam must be diluted with an equal volume of sterile water or sterile saline. When given IM, lorazepam is not to be diluted.
Adult: 1-4 mg slow IM/IV over 2-10 min; may be repeated in 15-20 min to a max dose of 8 mg

Pediatric (not FDA-approved): 0.05-0.1 mg/kg slow IV/IO/IM over 2 min; may be repeated once in 5-10 min to a max dose of 4 mg; 0.1-0.2 mg/kg (rectal dose)

SPECIAL CONSIDERATIONS

Pregnancy safety: Category D
Monitor respiratory rate and blood pressure during administration.
Have suction and intubation equipment available.
Inadvertent intraarterial injection may produce arteriospasm, resulting in gangrene that may require amputation.
Lorazepam expires in 6 weeks when not refrigerated; do not use if discolored or if solution contains precipitate.

MAGNESIUM SULFATE

CLASS

Electrolyte, anticonvulsant

DESCRIPTION

Magnesium sulfate reduces striated muscle contractions and blocks peripheral neuromuscular transmission by reducing acetylcholine release at the myoneural junction. In emergency care, magnesium sulfate is used in the management of seizures associated with toxemia of pregnancy. Other uses of magnesium sulfate include uterine relaxation (to inhibit contractions of premature labor), as a bronchodilator after beta-agonist and anticholinergic agents have been used, and replacement therapy for magnesium deficiency. Magnesium sulfate is recommended for use in cardiac arrest only if torsades de pointes or suspected hypomagnesemia is present.

ONSET AND DURATION

Onset: (IV) Immediate; (IM) 3-4 hr
Duration: 30 min (IV); 3-4 hr (IM)

INDICATIONS

Seizures of eclampsia (toxemia of pregnancy)
Cardiac arrest only if torsades de pointes is suspected or hypomagnesemia is present
Life-threatening ventricular dysrhythmias attributable to digitalis toxicity
Suspected hypomagnesemia
Status asthmaticus not responsive to beta-adrenergic drugs

CONTRAINDICATIONS

Heart block or myocardial damage

ADVERSE REACTIONS

Diaphoresis
Facial flushing
Hypotension
Depressed reflexes
Hypothermia
Reduced heart rate
Circulatory collapse
Respiratory depression
Diarrhea
Nausea and vomiting

DRUG INTERACTIONS

Central nervous system depressant effects may be enhanced if the patient is taking other central nervous system depressants.
Serious changes in cardiac function may occur with cardiac glycosides (avoid excess magnesium administration).

HOW SUPPLIED

10%, 12.5%, 50% solution in 40, 80, 100, and 125 mg/mL

DOSAGE AND ADMINISTRATION

Seizure Activity Associated With Pregnancy
Adult: 1-4 g (8-32 mEq) IV; max dose of 30-40 g/day
Pulseless Arrest (for Hypomagnesemia or Torsades de Pointes), Status Asthmaticus
Adult: 1-2 g (2-4 mL of a 50% solution) diluted in 10 mL of D_5W IV/IO push
Pediatric: 25-50 mg/kg IV/IO (max 2 g) over 10-20 min; over 15-30 min for status asthmaticus
Torsades de Pointes With Pulse or AMI With Hypomagnesemia
Adult: Loading dose of 1-2 g in 50-100 mL of D_5W over 5-60 min IV; follow with 0.5-1 g/hr IV (titrate dose to control torsades)
Pediatric: Same as pulseless arrest

SPECIAL CONSIDERATIONS

Pregnancy safety: Category A
Magnesium sulfate is administered for the treatment of toxemia of pregnancy. It is recommended that the drug not be administered in the 2 hr before delivery, if possible. IV calcium gluconate or calcium chloride should be available as an antagonist to magnesium if needed
Convulsions may occur up to 48 hr after delivery, necessitating continued therapy.
The "cure" for toxemia is delivery of the baby.
Magnesium must be used with caution in patients with renal failure because it is cleared by the kidneys and can reach toxic levels easily in those patients.

MANNITOL (OSMITROL)

CLASS

Osmotic diuretic

DESCRIPTION

Because of the osmotic properties of mannitol, the drug promotes the movement of fluid from the intracellular into the extracellular space. In emergency care, mannitol most often is used to decrease cerebral edema and intracranial pressure caused by head injury or mass lesions.

ONSET AND DURATION

Onset: 1-3 hr for diuretic effect; within 15 min for reduction of intracranial pressure
Duration: 4-6 hr for diuretic effect; 3-8 hr for reduction of intracranial pressure

INDICATIONS

Cerebral edema
Other causes of increased intracranial pressure (space-occupying lesions)
Rhabdomyolysis (myoglobinuria)
Blood transfusion reactions
Promoting urinary excretion of toxic substances

CONTRAINDICATIONS

Severe hypotension
Active intracranial bleeding
Dehydration
Hyponatremia
Severe pulmonary edema or congestion
Profound hypovolemia
Severe renal disease (anuria)

ADVERSE REACTIONS

Transient volume overload
Pulmonary edema
Renal failure
Congestive heart failure
Hypotension (from excessive diuresis)
Sodium depletion
Nausea and vomiting

DRUG INTERACTIONS

When given concurrently with digitalis glycosides, an increase in digitalis toxicity may develop.

HOW SUPPLIED

250 and 500 mL of a 20% solution for IV infusion (200 mg/mL); 25% solution in 50 mL for slow IV push

DOSAGE AND ADMINISTRATION

Adult: 0.5-1 g/kg in a 20% solution over 5-10 min through an in-line filter; usual adult dose is 20-200 g/24 hr. Additional doses of 0.25-2 g/kg can be given every 4-6 hr as needed
Pediatric: 0.2-0.5 g/kg dose IV infusion over 30-60 min (max dose: 1 g/kg) every 4-6 hr

SPECIAL CONSIDERATIONS

Pregnancy safety: Category C
Mannitol may crystallize at low temperatures and may need to be warmed in boiling water until clear (cool to body temperature before use).
In-line filter should always be used.
Use with support of oxygenation and ventilation.
Effectiveness depends on large doses and an intact blood-brain barrier.
The use of mannitol and its dosages in emergency care are controversial.

MEPERIDINE (DEMEROL)

CLASS

Opioid analgesic

DESCRIPTION

Meperidine is a synthetic opioid agonist that works at opioid receptors to produce analgesia and euphoria. Excessive doses can cause respiratory and central nervous system depression and seizures. It has high potential for physical dependence and abuse and is classified as a schedule II drug.

ONSET AND DURATION

Onset: (IM) 10-15 min; (IV) within 5 min
Duration: 2-4 hr

INDICATIONS

Moderate to severe pain
Preoperative medication
Obstetrical analgesia

CONTRAINDICATIONS

Hypersensitivity to narcotics
Patients taking MAO inhibitors or selective serotonin reuptake inhibitors
During labor or delivery of a premature infant
Head injury

ADVERSE REACTIONS

Respiratory depression
Nausea and vomiting
Euphoria
Delirium
Agitation
Hallucination
Seizures
Headache
Hypotension
Visual disturbances
Coma
Facial flushing
Circulatory collapse
Dysrhythmias
Allergic reaction
Drowsiness

DRUG INTERACTIONS

Respiratory depression, hypotension, or sedation may be potentiated by central nervous system depressants.
Therapeutic doses of meperidine have caused fatal reactions in patients taking MAO inhibitors within the previous 14 days.
Phenytoin may decrease analgesic effects.

HOW SUPPLIED

Parenteral: 25, 50, 100 mg/mL in 1- and 5-mL prefilled syringe and tubex

DOSAGE AND ADMINISTRATION

Adult: 50-100 mg IM every 3-4 hr as needed; 15-35 mg IV per hour (dose should be individualized)
Elderly: 25 mg IM every 4 hr as needed
Pediatric: 1-2 mg/kg dose IM every 3-4 hr as needed; maximum single dose not to exceed 100 mg

SPECIAL CONSIDERATIONS

Pregnancy safety: Category B (if not used for prolonged periods or in high doses at term)
Use with caution in patients with asthma and chronic obstructive pulmonary disease.
Meperidine may aggravate seizures in those with convulsive disorders (especially in patients with renal insufficiency).
Use with caution in those susceptible to central nervous system depression.
Naloxone should be readily available.
Protect from light and freezing.
Use with caution in patients with SVT

METHYLPREDNISOLONE (SOLU-MEDROL)

CLASS

Glucocorticoid

DESCRIPTION

Methylprednisolone is a synthetic steroid that suppresses acute and chronic inflammation. In addition, it potentiates vascular smooth muscle relaxation by beta-adrenergic agonists and may alter airway hyperactivity. It currently is used for reduction of posttraumatic spinal cord edema, but this indication is controversial.[2]

ONSET AND DURATION

Onset: 1-2 hr
Duration: 8-24 hr

INDICATIONS

Anaphylaxis
Bronchodilator: unresponsive asthma
Shock (controversial)
Acute spinal cord injury (controversial)
Adrenal insufficiency (hydrocortisone [Solu-Cortef] also may be used)

CONTRAINDICATIONS

Use with caution in patients with gastrointestinal bleeding, diabetes mellitus, or severe infection.

ADVERSE REACTIONS

Headache
Hypertension
Sodium and water retention
Hypokalemia
Alkalosis

DRUG INTERACTIONS

Hypoglycemic responses to insulin and oral hypoglycemic agents may be blunted.
Potassium-depleting agents may potentiate hypokalemia induced by corticosteroids.

HOW SUPPLIED

20, 40, 80 mg/mL; 125 mg/2 mL

DOSAGE AND ADMINISTRATION

Adult: Variable; usually within the range of 40-125 mg IV. (Higher doses for spinal cord injury, per medical direction.)
Pediatric: Loading dose: 1-2 mg/kg IV

SPECIAL CONSIDERATIONS

Pregnancy safety: Category C

METOCLOPRAMIDE (METOZOLV ODT, OCTAMIDE, REGLAN)

CLASS

Antiemetic, GI stimulant

DESCRIPTION

Metoclopramide enhances GI motility. The drug is chemically related to procainamide, but has no anesthetic or antidysrhythmic properties. Metoclopramide was originally developed to treat nausea during pregnancy but is also useful in the treatment of chemotherapy-induced nausea and vomiting.

ONSET AND DURATION

Onset: 30-60 min (oral); 1-3 min (IV); 10-15 min (IM)
Duration: 1-2 hr

INDICATIONS

Nausea
Vomiting

CONTRAINDICATIONS

Hypersensitivity to the drug or procainamide
GI obstruction, bleeding, or perforation

ADVERSE REACTIONS

CNS effects may occur
Confusion
Depression
Drowsiness
Cardiac conduction disturbances

Fatigue
Headache
Hypotension
Hypertension
Nausea
Insomnia
Tardive dyskinesia

DRUG INTERACTIONS

Metoclopramide can increase the rate or extent of absorption of other drugs (acetaminophen, aspirin) because of accelerated gastric emptying.
Digoxin absorption and bioavailability may be diminished in some patients.

HOW SUPPLIED

Tablet: 5, 10 mg
Oral solution: 5 mg/mL
Solution for injection: 5 mg/mL

DOSAGE AND ADMINISTRATION

Pregnant women: 5 mg PO every 8 hr as needed
Chemotherapy-induced nausea and vomiting:
IM: 10 mg; may be repeated in 4-6 hr as needed
IV: 1-2 mg/kg; may be repeated twice at 2-hr intervals
Children: Not recommended

SPECIAL CONSIDERATIONS

Pregnancy safety: Category B
Use with caution in patients with renal disease, such as renal failure or renal impairment, attributable to possible accumulation and toxicity.
Not recommended for patients with Parkinson's disease.
Concurrent use of ethanol can increase the CNS depressant effects of metoclopramide. Combined use of metoclopramide and other CNS depressants, such as anxiolytics, sedatives, and hypnotics, can increase possible sedation.

METOPROLOL (LOPRESSOR)

CLASS

Beta-blocking agent

DESCRIPTION

Beta-adrenergic blocking agents compete with beta-adrenergic agonists for available beta-receptor sites on the membrane of cardiac muscle, bronchial smooth muscle, and the smooth muscle of blood vessels. The $beta_1$-blocking action on the heart decreases heart rate, conduction velocity, myocardial contractility, and cardiac output. Metoprolol is used to control ventricular response in supraventricular tachydysrhythmias (paroxysmal supraventricular tachycardia, atrial fibrillation, atrial flutter). Metoprolol is considered a second-line agent after adenosine, diltiazem, or a digitalis derivative.

ONSET AND DURATION

Onset: 1-2 min
Duration: 3-4 hr

INDICATIONS

All patients with suspected MI and unstable angina in the absence of contraindications (can reduce the incidence of VF)
Useful as an adjunctive agent with fibrinolytic therapy (may reduce nonfatal reinfarction and recurrent ischemia)
To convert to normal sinus rhythm or to slow ventricular response (or both) in supraventricular tachydysrhythmias (reentry SVT, atrial fibrillation, or atrial flutter)
To reduce myocardial ischemia in AMI patients with elevated heart rate, blood pressure, or both

CONTRAINDICATIONS

Hemodynamically unstable patients
STEMI if signs of heart failure, low cardiac output, or increased risk for cardiogenic shock are present
Relative contraindications include P-R interval >0.24 sec, second- or third-degree heart block, active asthma, reactive airway disease, severe bradycardia, SBP <100 mm Hg

ADVERSE REACTIONS

Bradycardia
Atrioventricular conduction delays
Hypotension
Palpitations
Nausea and vomiting

DRUG INTERACTIONS

Metoprolol may potentiate antihypertensive effects when given to patients taking calcium channel blockers or MAO inhibitors.
Catecholamine-depleting drugs may potentiate hypotension.
Sympathomimetic effects may be antagonized; signs of hypoglycemia may be masked.

HOW SUPPLIED

1 mg/mL, 5 mg/5 mL ampules

DOSAGE AND ADMINISTRATION

Adult: 5 mg slow IV at 5-min intervals to a total of 15 mg
Pediatric: Safety not established

SPECIAL CONSIDERATIONS

Pregnancy safety: Category C
Metoprolol must be given slowly IV over 5 min.
Concurrent IV administration with IV calcium channel blockers such as verapamil or diltiazem can cause severe hypotension.
Metoprolol should be used with caution in persons with liver or renal dysfunction.

MIDAZOLAM HYDROCHLORIDE (VERSED)

CLASS

Short-acting benzodiazepine

DESCRIPTION

Midazolam hydrochloride is a water-soluble benzodiazepine that may be administered for conscious sedation to relieve apprehension or impair memory before tracheal intubation or cardioversion. The drug may also be used in the management of seizures in children.

ONSET AND DURATION

Onset: 1-3 min (IV); dose dependent
Duration: 2-6 hr; dose dependent

INDICATIONS

Premedication for tracheal intubation, cardioversion, or other painful procedures
Seizures in children when other benzodiazepines are not effective

CONTRAINDICATIONS

Hypersensitivity to midazolam
Glaucoma (relative)
Shock
Coma
Alcohol intoxication (relative; may be used for alcohol withdrawal)
Depressed vital signs
Concomitant use of barbiturates, alcohol, narcotics, or other central nervous system depressants

ADVERSE REACTIONS

Respiratory depression
Hiccups
Cough
Oversedation
Pain at the injection site
Nausea and vomiting
Headache
Blurred vision
Fluctuations in vital signs
Hypotension
Respiratory arrest

DRUG INTERACTIONS

Sedative effect of midazolam may be accentuated by concomitant use of barbiturates, alcohol, or narcotics (and therefore should not be used in patients who have taken central nervous system depressants).

HOW SUPPLIED

2-, 5-, 10-mL vials (1 mg/mL)
1-, 2-, 5-, 10-mL vials (5 mg/mL)

DOSAGE AND ADMINISTRATION

Sedation
Adult: 1-2.5 mg slow IV (over 2-3 min); may be repeated if necessary in small increments (total max dose not to exceed 0.1 mg/kg)
Elderly: 0.5 mg slow IV (max: 1.5 mg in a 2-min period)
Pediatric: Loading dose: 0.05-0.2 mg/kg; then continue infusion 1-2 mcg/kg/min
Seizures in children: 0.1-0.15 mg/kg (max dose 5 mg) IV slow over 1-2 min or IM
Rapid Sequence Intubation
0.1-0.3 mg/kg IV/IO; max single dose: 10 mg

SPECIAL CONSIDERATIONS

Pregnancy safety: Category D
Never administer medication as IV bolus.
NOTE: Midazolam has been associated with respiratory depression and respiratory arrest when used for sedation. Its use requires continuous monitoring of respiratory and cardiac function. Emergency airway equipment should be readily available.

MORPHINE SULFATE (ASTRAMORPH/PF AND OTHERS)

CLASS

Opioid analgesic

DESCRIPTION

Morphine sulfate is a natural opium alkaloid that has a primary effect of analgesia. It also increases peripheral venous capacitance and decreases venous return (chemical phlebotomy). Morphine sulfate causes euphoria and respiratory and central nervous system depression. Secondary pharmacological effects of morphine include depressed responsiveness of alpha-adrenergic receptors (producing peripheral vasodilation) and baroreceptor inhibition. In addition, because morphine decreases preload and afterload, it may decrease myocardial oxygen demand. The properties of this medication make it extremely useful in emergency care. Morphine sulfate is a schedule II drug.

ONSET AND DURATION

Onset: 1-2 min after administration
Duration: 2-7 hr

INDICATIONS

Chest pain associated with ACS unresponsive to nitrates
Acute cardiogenic pulmonary edema (with adequate blood pressure), with or without associated pain
Moderate to severe acute and chronic pain

CONTRAINDICATIONS

Hypersensitivity to narcotics
Hypovolemia
Hypotension
Head injury or undiagnosed abdominal pain

Increased intracranial pressure
Severe respiratory depression
Patients who have taken MAO inhibitors within 14 days
Use with caution in RV infarction

ADVERSE REACTIONS

Hypotension in volume-depleted patients
Tachycardia
Bradycardia
Palpitations
Syncope
Facial flushing, diaphoresis, pruritus
Respiratory depression
Euphoria
Bronchospasm
Dry mouth
Allergic reaction

DRUG INTERACTIONS

Central nervous system depressants may potentiate effects of morphine (respiratory depression, hypotension, sedation).
Phenothiazines may potentiate analgesia.
MAO inhibitors may cause paradoxical excitation.

HOW SUPPLIED

Morphine is supplied in tablets, suppositories, and solution. In emergency care, morphine sulfate usually is administered IV.
Parenteral preparations are available in many strengths. A common preparation is 10 mg in 1 mL of solution, ampules and Tubex syringes.

DOSAGE AND ADMINISTRATION

Adult:
- STEMI: 2-4 mg IV; may give additional doses of 2-8 mg IV at 5- to 15-min intervals
- UA/NSTEMI: 1-5 mg IV only if symptoms not relieved by nitrates or if symptoms recur (use with caution)
- Pain: 2-4 mg slow IV over 1-5 min every 5-30 min; titrated to effect

Pediatric: 0.1-0.2 mg/kg dose IV (max total dose: 15 mg)

SPECIAL CONSIDERATIONS

Pregnancy safety: Category B (if not used for prolonged periods or in high doses at term); narcotics rapidly cross the placenta
Safety in neonates has not been established.
Use with caution in the elderly, in those with asthma, and in those susceptible to central nervous system depression.
Morphine should be used with caution in chronic pain syndromes.
Morphine may worsen bradycardia or heart block in inferior myocardial infarction (vagotonic effect).
Naloxone (0.4-2 mg IV) should be readily available.

NALOXONE (NARCAN)

CLASS

Opioid antagonist

DESCRIPTION

Naloxone is a competitive narcotic antagonist used in the management of known or suspected overdose caused by narcotics. Naloxone antagonizes all actions of morphine. Naloxone is the preferred first-line agent in suspected opioid overdose unresponsive to oxygen and support of ventilation.

ONSET AND DURATION

Onset: Within 2 min
Duration: 30-60 min

INDICATIONS

For the complete or partial reversal of central nervous system and respiratory depression induced by opioids including the following:

Narcotic Agonist
- Morphine sulfate
- Heroin
- Hydromorphone
- Methadone
- Meperidine
- Paregoric
- Fentanyl citrate
- Oxycodone
- Codeine

Narcotic Agonist/Antagonist
- Butorphanol tartrate
- Pentazocine
- Nalbuphine

Decreased Level of Consciousness
Coma of Unknown Origin

CONTRAINDICATIONS

Hypersensitivity
Use with caution in narcotic-dependent patients who may experience withdrawal syndrome (including neonates of narcotic-dependent mothers).
Avoid use in meperidine-induced seizures

ADVERSE REACTIONS

Tachycardia
Hypertension
Dysrhythmias
Nausea and vomiting
Diaphoresis
Blurred vision
Withdrawal (opiate)

DRUG INTERACTIONS

Incompatible with bisulfite and alkaline solutions

HOW SUPPLIED

0.4 mg/mL (1, 10 mL); 1 mg/mL (2-mL) vials

DOSAGE AND ADMINISTRATION

Adult:

- Typical IV (or endotracheal tube diluted) dose: 0.4-mg; titrate until ventilation is adequate. Use higher doses (up to 2 mg) for complete narcotic reversal. Can administer up to 6-10 mg over short period (<10 min). For respiratory depression from sedation, smaller doses of 0.4 mg repeated every 2-3 min may be used. For chronic opioid-addicted patients use smaller doses and titrate slowly.
- IM/subQ dose: 0.4-0.8 mg

Pediatric:

- 0.1 mg/kg IV/IO/ET (diluted) every 2 min as needed for total reversal of narcotic effects (max 2 mg); if total reversal is not required, smaller doses (0.001-0.005 mg/kg) may be used, titrated to effect.
- Pediatric IV/IO infusion: 0.002-0.16 mg/kg (2-160 mcg/kg) per hour

SPECIAL CONSIDERATIONS

Pregnancy safety: Category C

Some research has demonstrated the efficacy of intranasal naloxone administration; however, the optimal dose for the intranasal route has not been established.

Seizures have been reported (no causal relationship has been established).

Naloxone may not reverse hypotension.

Exercise caution and use smaller doses when administering naloxone to narcotic addicts (may precipitate withdrawal with hypertension, tachycardia, and violent behavior).

Rare anaphylactic reactions have been reported.

NITROGLYCERIN (NITROSTAT AND OTHERS)

CLASS

Vasodilator

DESCRIPTION

Nitrates and nitrites dilate arterioles and veins in the periphery (and coronary arteries in high doses). The resultant reduction in preload, and to a lesser extent in afterload, decreases the workload of the heart and lowers myocardial oxygen demand. Nitroglycerin is lipid soluble and is thought to enter the body from the gastrointestinal tract through the lymphatics rather than the portal blood.

ONSET AND DURATION

Onset: 1-3 min

Duration: 30-60 min

INDICATIONS

Ischemic chest pain

Congestive heart failure

AMI (large anterior wall infarction, persistent or recurrent ischemia, hypertension)

Hypertensive emergencies with ACS

CONTRAINDICATIONS

Volume depletion

Hypersensitivity

Hypotension (SBP <90 mm Hg or ≥30 mm Hg below baseline)

Head injury

Extreme bradycardia (HR <50 beats/min)

Extreme tachycardia (HR >100 beats/min) in the absence of heart failure

Right ventricular infarction

Cerebral hemorrhage

Recent use of tadalafil (Cialis), vardenafil (Levitra), or sildenafil (Viagra)

Aortic stenosis

ADVERSE REACTIONS

Transient headache

Reflex tachycardia

Hypotension

Nausea and vomiting

Postural syncope

Diaphoresis

Flushing

DRUG INTERACTIONS

Other vasodilators may have additive hypotensive effects.

Do not mix with other drugs.

HOW SUPPLIED

Tablets: 0.15 mg (1/400 gr), 0.3 mg (1/200 gr), 0.4 mg (1/150 gr), 0.6 (1/100 gr), and extended-release capsules and transdermal preparations

Metered spray: 0.4 mg per spray (do not shake)

Parenteral: 5 mg/mL; 10, 20, 40 mg/100 mL

DOSAGE AND ADMINISTRATION

Adult:

- Tablet: 0.3-0.4 mg sublingually; may repeat for a total of 3 doses at 5-min intervals
- Metered spray: 1-2 sprays (0.4 mg/dose) for 0.5-1 sec at 5-min intervals; max 3 sprays within 15 min

Infusion: Begin at a rate of 10 mcg/min; increase by 10 mcg/min q 3-5 min until desired effect is achieved; ceiling dose of 200 mcg/min commonly used
Pediatric (continuous infusion): Initial dose 0.25-0.5 mcg/kg/min; titrate by 1 mcg/kg/min every 15-20 min; typical dose range: 1-5 mcg/kg/min

SPECIAL CONSIDERATIONS

Pregnancy safety: Category C
Nitroglycerin is associated with increased susceptibility to hypotension in the elderly.
Nitroglycerin decomposes when exposed to light or heat.
Nitroglycerin must be kept in airtight containers.
Active ingredient of nitroglycerin will "sting" when administered sublingually.
Use with extreme caution in patients with inferior acute myocardial infarction with possible right ventricular involvement.
Administer IV nitroglycerin by infusion pump to ensure precise flow rate.
PVC tubing may absorb up to 80% of available drug; non-PVC tubing should be used.

NITROPASTE (NITRO-BID OINTMENT)

CLASS

Vasodilator

DESCRIPTION

Nitropaste contains a 2% solution of nitroglycerin in an absorbent paste.

ONSET AND DURATION

Onset: 15-60 min
Duration: 2-12 hr

INDICATIONS

Angina pectoris
Chest pain associated with acute myocardial infarction (less easily titratable than IV nitroglycerin)

CONTRAINDICATIONS

Same as those for nitroglycerin
Hypersensitivity
Hypotension
Head injury
Cerebral hemorrhage

ADVERSE REACTIONS

Transient headache
Postural syncope
Reflex tachycardia
Hypotension
Nausea and vomiting
Allergic reaction

DRUG INTERACTIONS

Other vasodilators may have additive hypotensive effects.

HOW SUPPLIED

20-, 60-g tubes of 2% nitroglycerin paste (measuring applicators are supplied)

DOSAGE AND ADMINISTRATION

Adult: Apply 1-2 inches over 2- to 4-inch area of skin that is free of hair (usually the chest wall); cover with transparent wrap and secure with tape
Pediatric: Not recommended

SPECIAL CONSIDERATIONS

Pregnancy safety: Category C
Wear gloves when applying paste.
Do not massage or rub paste (rapid absorption will interfere with the sustained action of the drug).
Store paste in a cool place with the tube tightly capped.
Although the adverse effects for nitropaste are the same as those for sublingually administered nitroglycerin, their frequency and severity usually are considerably less with the sustained-release preparations because of the slower absorption and less erratic serum levels.

NITROPRUSSIDE

CLASS

Vasodilator

DESCRIPTION

Nitroprusside is an intravenous hypotensive agent effective in the acute management of hypertensive crisis and in the management of congestive heart failure. Nitroprusside-induced peripheral vasodilation results in a reduced left ventricular afterload. This, along with a reduced venous return to the heart, causes a slight increase in heart rate and decrease in cardiac output in hypertensive patients. In patients with congestive heart failure, nitroprusside improves left ventricular heart performance, increasing cardiac output and stroke volume. The peripheral vasodilatory effects of nitroprusside are due to a direct action of the drug on arterial and venous smooth muscle.

ONSET AND DURATION

Onset: Immediate
Duration: 1-10 min following infusion

INDICATIONS

Heart failure
Hypertensive emergency
Hypotension induction

CONTRAINDICATIONS

Aortic coarctation
AV shunt
High-output cardiac failure

Hypotension
Hypovolemia
Increased ICP
Pulmonary or renal disease
Cyanide toxicity
Recent ingestion of drugs for erectile dysfunction (e.g., sildenafil)

ADVERSE REACTIONS

Abdominal pain
Ataxia
Bradycardia
Coma
Confusion
Cyanide toxicity
Diaphoresis
Dizziness
Dyspnea
Flushing
Headache
Hyperreflexia
Hypotension
Increased ICP
Muscle cramps
Seizures
Syncope
Tachycardia
Vomiting

DRUG INTERACTIONS

Additive hypotensive effects may occur when nitroprusside is used concomitantly with other antihypertensive agents, general anesthetics, ganglionic blocking agents, and negative inotropic agents.
Sympathomimetics, such as cocaine, dobutamine, dopamine, norepinephrine, epinephrine, and others, may antagonize the antihypertensive effects of nitroprusside when administered concomitantly.
Additive hypotensive effects may be seen when MAOIs are combined with antihypertensives or medications with hypotensive properties.

HOW SUPPLIED

50 mg/2 mL for injection: Must be diluted with dextrose 5% in water (D_5W) before administration. Do not administer by direct injection. Administer diluted solution by IV infusion using a controlled infusion device.

DOSAGE AND ADMINISTRATION

Adults and children: Begin at 0.1 mcg/kg/min and titrate upward every 3-5 min to desired effect (usually up to 5 mcg/kg/min, but higher doses up to 10 mcg/kg/min may be needed). Infusion is titrated to desired blood pressure and/or cardiac output.

SPECIAL CONSIDERATIONS

Pregnancy safety: Category C
Nitroprusside should be used only when appropriate monitoring equipment and personnel are available; blood pressure should be continuously monitored.
Use of infusion pump is strongly advised.
Cyanide toxicity or methemoglobinemia may occur with prolonged administration.
Use lower end dosage range for elderly patients.
Protect nitroprusside from light.

NITROUS OXIDE/OXYGEN (50:50) (NITRONOX)

CLASS

Gaseous analgesic/anesthetic

DESCRIPTION

Nitrous oxide/oxygen is a blended mixture of 50% nitrous oxide and 50% oxygen. When inhaled, nitrous oxide/oxygen depresses the central nervous system, causing anesthesia. In addition, the high concentration of oxygen delivered along with the nitrous oxide increases oxygen tension in the blood, thereby reducing hypoxia. Nitrous oxide/oxygen is self-administered.

ONSET AND DURATION

Onset: 2-5 min
Duration: 2-5 min

INDICATIONS

Moderate to severe pain
Anxiety
Apprehension

CONTRAINDICATIONS

Impaired level of consciousness
Head injury
Chest trauma (pneumothorax)
Inability to comply with instructions
Decompression sickness (nitrogen narcosis, air embolus, air transport)
Undiagnosed abdominal pain or marked distention
Bowel obstruction
Hypotension
Shock
Chronic obstructive pulmonary disease (with history or suspicion of CO_2 retention)

ADVERSE REACTIONS

Dizziness
Apnea
Cyanosis

Nausea and vomiting
Malignant hyperthermia (rare but dangerous)

DRUG INTERACTIONS

None significant

HOW SUPPLIED

D and E cylinders (blue and white in Canada, blue and green in United States) of 50% nitrous oxide and 50% oxygen compressed gas

DOSAGE AND ADMINISTRATION

Adult: Invert cylinder several times before use; instruct the patient to inhale deeply through a patient-held mask or mouthpiece
Pediatric: Same as adult

SPECIAL CONSIDERATIONS

Pregnancy safety: Nitrous oxide has been shown to increase the incidence of spontaneous abortion.
Nitrous oxide is 34 times more soluble than nitrogen and will diffuse into pockets of trapped gas in the patient (intestinal obstruction, pneumothorax, blocked middle ear).
As the nitrogen leaves and is replaced by larger amounts of nitrous oxide, increased pressures or volumes may cause serious damage, for example, intestinal rupture.
Nitrous oxide is a nonexplosive gas.
Patient must hold mask and self-administer.

NOTE
When delivering nitrous oxide and oxygen from a single tank, the paramedic must ensure that enough oxygen remains in the tank to provide adequate oxygenation. Inverting the cylinder several times to mix the gases is important for this reason. Monitoring of oximetry during administration of nitrous oxide also is reasonable.

NOREPINEPHRINE (LEVOPHED)

CLASS

Sympathomimetic

DESCRIPTION

Norepinephrine is an alpha- and $beta_1$-adrenergic agonist. Norepinephrine is a potent vasoconstrictor that also increases myocardial contractility. Because norepinephrine tends to constrict the renal and mesenteric blood vessels, it rarely is used in the prehospital setting. It is an agent of last resort for management of ischemic heart disease and shock.

ONSET AND DURATION

Onset: 1-3 min
Duration: 5-10 min

INDICATIONS

Severe cardiogenic shock
Neurogenic shock
Inotropic support
Hemodynamically significant hypotension (SBP <70 mm Hg) with low total peripheral resistance, refractory to other sympathomimetic amines

CONTRAINDICATIONS

Hypotensive patients with hypovolemia (relative contraindication)

ADVERSE REACTIONS

Headache
Dysrhythmias
Tachycardia
Reflex bradycardia
Angina pectoris
Hypertension

DRUG INTERACTIONS

Norepinephrine can be deactivated by alkaline solutions.
MAO inhibitors and bretylium may potentiate the effects of catecholamines.
Beta-adrenergic antagonists may blunt inotropic response.
Sympathomimetics and phosphodiesterase inhibitors may exacerbate dysrhythmia response.

HOW SUPPLIED

1 mg/mL, 4-mL ampule

DOSAGE AND ADMINISTRATION

Adult: Dilute 4 mg in 250 mL of D_5W or D_5NS (16 mcg/mL); begin infusion at 0.1-0.5 mcg/kg/min (up to 30 mcg/min) titrated to desired effect (average adult dose is 7-35 mcg/min); poison/drug-induced hypotension may require higher doses to achieve adequate perfusion
Pediatric: Begin at 0.1-2 mcg/kg/min IV/IO; adjust infusion rate to achieve desired change in blood pressure and systemic perfusion.

SPECIAL CONSIDERATIONS

Pregnancy safety: Category C
Norepinephrine may cause fetal anoxia when used in pregnancy.
Infuse norepinephrine through a large, stable vein to avoid extravasation and tissue necrosis.
Use infusion pump to ensure precise flow rate.
Do not administer in same IV line as alkaline solutions.
May induce dysrhythmias.

ONDANSETRON (ZOFRAN, ZUPLENZ)

CLASS

Antiemetic

DESCRIPTION

Ondansetron is an oral and parenteral antiemetic agent. It is the first selective serotonin blocking agent to be marketed. The primary use of the drug is to manage nausea and vomiting in postoperative patients and in those undergoing chemotherapy. Ondansetron preferentially blocks the serotonin 5-HT_3 receptors. These receptors are found centrally in the chemoreceptor trigger zone and peripherally at vagal nerve terminals in the intestines.

ONSET AND DURATION

Onset: Within 30 min
Duration: 3-6 hr

INDICATIONS

Nausea
Vomiting

CONTRAINDICATIONS

Hypersensitivity to the drug
Liver disease
GI obstruction

ADVERSE REACTIONS

Generally well tolerated
ECG irregularities (rare)
Hiccups
Pruritus
Flushing
Chills
Headache
Dizziness
Drowsiness
Extrapyramidal symptoms
Shivering
Hypoxia

DRUG INTERACTIONS

None significant in emergency care

HOW SUPPLIED

Tablet: 4, 8, 24 mg
Dissolving film and tablets: 4, 8 mg
Oral solution: 4 mg/5 mL
Solution for injection: 2 mg/mL

DOSAGE AND ADMINISTRATION (ADULT; PARENTERAL, ORAL)

IV: Up to 4 mg may be given undiluted; inject over 30 sec (2-5 min preferred)
Infusion (available in a premix or dilute dose in 50 mL of D_5W): Infuse over 15 min
IM: 4 mg, single injection in well-developed muscle
Oral film and tablets: Adults 4 mg PO
Safety in children not established.

SPECIAL CONSIDERATIONS

Pregnancy safety: Category B
The use of ondansetron may mask the symptoms of adynamic ileus, GI obstruction, or gastric distention after abdominal surgery.
Tablets should be gently removed from foil; not pushed through package. Allow to dissolve on tongue with saliva.

OXYGEN

CLASS

Naturally occurring atmospheric gas

DESCRIPTION

Oxygen is an odorless, tasteless, colorless gas that is present in room air at a concentration of approximately 21%. Oxygen is an important emergency drug used to reverse hypoxemia; in doing so, it helps oxidize glucose to produce adenosine triphosphate (aerobic metabolism). Oxygen may help reduce the size of infarcted tissue during an acute myocardial infarction (in patients who are hypoxemic on room air).

ONSET AND DURATION

Onset: Immediate
Duration: Less than 2 min

INDICATIONS

Any suspected cardiopulmonary emergency
Confirmed or suspected hypoxia
Ischemic chest pain
Respiratory insufficiency
Suspected stroke or ACS with hypoxemia (when oxygen saturation is unknown or <94%)
Prophylactically during air transport
Confirmed or suspected carbon monoxide poisoning and other causes of decreased tissue oxygenation (cardiac arrest)

CONTRAINDICATIONS

Oxygen should never be withheld in any critically ill patient.

ADVERSE REACTIONS

High-concentration oxygen may cause decreased level of consciousness and respiratory depression in patients with chronic carbon dioxide retention.

DRUG INTERACTIONS

None significant

HOW SUPPLIED

Oxygen cylinders (usually green and white) or wall-mounted delivery devices that supply 100% compressed oxygen gas

DOSAGE AND ADMINISTRATION

Adult and child:
- Administer highest possible concentration during initial evaluation and stabilization; then administer to maintain oxygen saturation of 94-99%
- High-concentration: 10-15 L/min via nonrebreather mask or high-flow oxygen delivery device
- Low concentration: 1-4 L/min via nasal cannula
- Venturi mask concentrations (e.g., 24%, 28%, 32%, 36%) for intermediate rates of oxygen administration in patients with chronic obstructive pulmonary disease

SPECIAL CONSIDERATIONS

Pregnancy safety: NA
Oxygen vigorously supports combustion.

OXYTOCIN (PITOCIN)

CLASS

Pituitary hormone

DESCRIPTION

Oxytocin means "rapid birth" and is a synthetic hormone named for the natural posterior pituitary hormone. It stimulates uterine smooth muscle contractions and helps expedite the normal contractions of a spontaneous labor. As with all significant uterine contractions, a transient reduction in uterine blood flow occurs. Oxytocin also stimulates the mammary glands to increase lactation, without increasing the production of milk. The drug is administered in the prehospital setting to control postpartum bleeding.

ONSET AND DURATION

Onset: (IV) Immediate; (IM) within 3-5 min
Duration: (IV) 20 min after the infusion is stopped; (IM) 30-60 min

INDICATIONS

Postpartum hemorrhage after infant and placental delivery

CONTRAINDICATIONS

Hypertonic or hyperactive uterus
Presence of a second fetus
Fetal distress

ADVERSE REACTIONS

Hypotension
Tachycardia
Hypertension
Dysrhythmias
Angina pectoris
Anxiety
Seizure
Nausea and vomiting
Allergic reaction
Uterine rupture (from excessive administration)

DRUG INTERACTIONS

Vasopressors may potentiate hypertension

HOW SUPPLIED

10 USP units/1-mL ampule (10 units/mL) and prefilled syringe 5 USP units/1-mL ampule (5 units/mL) and prefilled syringe

DOSAGE AND ADMINISTRATION

Control of Postpartum Hemorrhage
IM: 3-10 units IM following delivery of placenta
Bleeding Following Incomplete or Elective Abortion
IV: Mix 10-40 units (1-4 mL) in 1000 mL of NS or lactated Ringer's; infuse at 10-40 milliunits/min via microdrip tubing, titrated to severity of bleeding and uterine response

SPECIAL CONSIDERATIONS

Pregnancy safety: Category X
Vital signs and uterine tone should be monitored closely.
Oxytocin should be administered only in the prehospital setting after delivery of all fetuses.

PANCURONIUM

CLASS

Neuromuscular blocker (nondepolarizing)

DESCRIPTION

Pancuronium produces complete muscular relaxation by binding to the receptor for acetylcholine at the neuromuscular junction, without initiating depolarization of the muscle membrane. As the concentration of acetylcholine rises in the neuromuscular junction, pancuronium is displaced and muscle tone is regained. Neuromuscular blocking agents are used to provide muscle relaxation during surgery (particularly relaxation of the abdominal muscles) usually with general anesthesia and to prevent convulsive muscle spasms during electroconvulsive therapy. In emergency care, pancuronium is used to optimize conditions for endotracheal intubation and assisted ventilations.

ONSET AND DURATION

Onset: Paralysis in 3-5 min
Duration: 45-60 min

INDICATIONS

Induction or maintenance of paralysis after intubation to assist ventilations

CONTRAINDICATIONS

Known hypersensitivity to the drug
Inability to control airway and/or support ventilations with oxygen and positive pressure
Neuromuscular disease (e.g., myasthenia gravis)

ADVERSE REACTIONS

Transient hypotension
Tachycardia
Dysrhythmias
Hypertension
Excessive salivation
Pain, burning at IV injection site

DRUG INTERACTIONS

Positive chronotropic drugs may potentiate tachycardia.

HOW SUPPLIED

1, 2 mg/mL

DOSAGE AND ADMINISTRATION

Adult: 0.04-0.1 mg/kg slow IV; repeat q 30-60 min prn
Pediatric: 0.04-0.1 mg/kg slow IV
Newborn: 0.02 mg/kg dose

NOTE
If the patient is conscious, explain the effects of the medication before administration, and always sedate the patient before using a neuromuscular blocking agent.

SPECIAL CONSIDERATIONS

Pregnancy safety: Category C
Patients must be sedated completely and have an artificial airway during paralysis.
Carefully monitor the patient and be prepared to resuscitate.
The effects of pancuronium are antagonized by neostigmine (Prostigmin) 0.05 mg/kg and should be accompanied by atropine (0.6-1.2 mg IV).
Pancuronium has no effect on consciousness or pain.
Pancuronium will not stop neuronal seizure activity or decrease central nervous system damage caused by seizures.
Heart rate and cardiac output will be increased.
Pancuronium is excreted in the urine; doses should be decreased for patients with renal disease.

NOTE
Neuromuscular blocking agents produce respiratory paralysis. Therefore intubation and ventilatory support must be readily available.

Neuromuscular blocking agents produce respiratory paralysis. Therefore intubation and ventilatory support must be readily available.

PHENYTOIN (DILANTIN)

CLASS

Anticonvulsant

DESCRIPTION

Phenytoin (a hydantoin) is a drug used to control grand mal and focal motor seizure activity when other drugs are not successful. It was developed as an alternative anticonvulsant that would cause less sedation than barbiturates. Phenytoin appears to inhibit the spread of seizure activity by promoting sodium efflux from neurons, thereby stabilizing the threshold of the neuron against excitability caused by excess stimulation. Phenytoin also has been used to treat digitalis-induced atrial and ventricular dysrhythmias by stabilizing the sodium influx in Purkinje fibers of the heart, decreasing abnormal ventricular automaticity, and increasing atrioventricular node conduction.

ONSET AND DURATION

Onset: 20-30 min for seizure disorder
Duration: Several days

INDICATIONS

Major motor seizures (generalized grand mal, simple partial. and complex partial seizures)
Status epilepticus

CONTRAINDICATIONS

Hypersensitivity
Sinus bradycardia
Second- and third-degree heart block
Sinoatrial block

ADVERSE REACTIONS

Hypotension with rapid IV push (greater than 50 mg/min)
Cardiovascular collapse (with rapid IV use)
Dysrhythmias
Bradycardia
Respiratory depression
Central nervous system depression
Ataxia
Nystagmus
Thrombophlebitis
Nausea and vomiting
Pain from injection site

DRUG INTERACTIONS

Anticoagulants, cimetidine, sulfonamides, and salicylates may increase serum phenytoin levels.
Chronic alcohol consumption or use induces metabolism of the drug.
Lidocaine, propranolol, and other beta-blocking agents may increase cardiac depressant effects.
Xanthines may result in decreased phenytoin absorption.
Precipitation may occur when mixed with D_5W.
Phenytoin is incompatible with many solutions and medications.
Anticoagulation is enhanced with warfarin administration.

HOW SUPPLIED

50 mg/mL in 2- and 5-mL ampules, 2-mL prefilled syringe. May be diluted in NS (1-10 mg/mL, per protocol); use in-line filter
IV line should be flushed with 0.9% NS before and after the drug is administered

DOSAGE AND ADMINISTRATION

Seizures
Adult: 1000 mg or 15-20 mg/kg (usual loading dose) slow IV; not to exceed 1 g or rate of 50 mg/min; followed by 100-150 mg/dose at 30-min intervals (max of 1500 mg/24 hr)
Pediatric: 10-20 mg/kg slow IV (<0.5 mg/kg/min) loading dose

SPECIAL CONSIDERATIONS

Pregnancy safety: Category D
Phenytoin normally may have slight yellow color.
Carefully monitor vital signs.
Venous irritation can occur because of the alkalinity of the solution.
Use with caution in patients with pulmonary, cardiovascular, hepatic, or renal insufficiency.
Use large, stable vein for injection (extravasation may cause tissue necrosis).

PRALIDOXIME (2-PAM, PROTOPAM)

CLASS

Cholinesterase reactivator and antidote

DESCRIPTION

Pralidoxime reactivates the enzyme acetylcholinesterase, which allows acetylcholine to be degraded, thus relieving the parasympathetic overstimulation caused by excess acetylcholine. This drug is sometimes combined with atropine in an autoinjector such as the DuoDote autoinjector kit.

ONSET AND DURATION

Onset: Within minutes
Duration: Variable

INDICATIONS

Organophosphate poisoning (after atropine)

CONTRAINDICATIONS

Hypersensitivity to pralidoxime

ADVERSE REACTIONS

Tachycardia
Hypertension
Laryngospasm
Hyperventilation
Muscle weakness
Nausea

DRUG INTERACTIONS

Pralidoxime should not be mixed in the same syringe or solution with any other drug.

HOW SUPPLIED

Emergency single-dose kit containing a 20-mL vial of 1 g of the sterile drug, a 20-mL ampule of sterile diluent, and a 20-mL syringe with needle

DOSAGE AND ADMINISTRATION

Adult: 600 mg IM (usually by autoinjector) or 1-2 g IV over 15-30 min
Pediatric: 20-50 mg/kg IV over 15-30 min

SPECIAL CONSIDERATIONS

Pregnancy safety: Category C
Each 1 g of sterile powder is diluted with 20 mL of sterile water for injection.
Pralidoxime should be diluted further in 100 mL of NS and given as an IV infusion. Use promptly after reconstitution.
Medical direction may recommend the almost simultaneous administration of atropine.
Pralidoxime is not recommended in carbamate poisoning.
Reduce dosage in cases of known renal insufficiency.

PROCAINAMIDE

CLASS

Antidysrhythmic (Class IA)

DESCRIPTION

Procainamide suppresses phase 4 depolarization in normal ventricular muscle and Purkinje fibers, reducing the automaticity of ectopic pacemakers. It also suppresses reentry dysrhythmias by slowing intraventricular conduction. Procainamide may be effective in treating premature ventricular contractions and recurrent ventricular tachycardia that cannot be controlled with lidocaine.

ONSET AND DURATION

Onset: 10-30 min
Duration: 3-6 hr

INDICATIONS

Numerous dysrhythmias, including stable monomorphic VT with normal Q-T interval and preserved LV function
Reentry SVT uncontrolled by adenosine and vagal maneuvers if normotensive
Stable wide-complex tachycardia of unknown origin
Atrial fibrillation with rapid rate in WPW syndrome

CONTRAINDICATIONS

Second- and third-degree atrioventricular block (without functioning artificial pacemaker)

Digitalis toxicity
Torsades de pointes
Complete heart block
Tricyclic antidepressant toxicity

ADVERSE REACTIONS

Hypotension in patients with impaired LV function
Bradycardia
Reflex tachycardia
Atrioventricular block
Widened QRS complex
Prolonged P-R or Q-T interval
Premature ventricular contractions
Ventricular tachycardia, ventricular fibrillation, asystole
Central nervous system depression
Confusion
Seizure

DRUG INTERACTIONS

Increases effects of skeletal muscle relaxants.
Increases plasma/N-acetylprocainamide (active metabolites) concentrations with cimetidine, ranitidine, beta blockers, amiodarone, trimethoprim, and quinidine.
Use with caution with other drugs that prolong the Q-T interval (e.g., amiodarone).

HOW SUPPLIED

1 g in 10-mL vial (100 mg/mL)
1 g in 2-mL vials (500 mg/mL) for infusion

DOSAGE AND ADMINISTRATION

Adult: 20 mg/min slow IV infusion in recurrent ventricular fibrillation/pulseless ventricular tachycardia (max total: 17 mg/kg; max dose usually 1 g). In urgent situations, up to 50 mg/min may be given to a total dose of 17 mg/kg.
Other indications: 20 mg/min IV infusion until one of the following occurs: dysrhythmia resolves, hypotension, QRS widens by >50% of original width, total dose of 17 mg/kg
Maintenance: Infusion (after resuscitation from cardiac arrest): mix 1 g in 250 mL of solution in D_5W or NS (4 mg/mL), infuse at 1-4 mg/min
Pediatric: Loading dose 15 mg/kg IV/IO; infuse over 30-60 min

SPECIAL CONSIDERATIONS

Pregnancy safety: Category C
Procainamide has potent vasodilating and negative inotropic effects.
Rapid injection may cause procainamide-induced hypotension.
Carefully monitor vital signs and electrocardiogram (a small amount of QRS complex widening is expected).
Reduce dose in patients with cardiac or renal dysfunction to maximum total dose of 12 mg/kg and maintenance infusion to 1-2 mg/min.
Administer cautiously to patients with asthma, digitalis-induced dysrhythmias, acute myocardial infarction, or cardiac, hepatic, or renal insufficiency.

NOTE
Discontinue if the dysrhythmia is suppressed, hypotension develops, the QRS complex is widened by 50% of its original width, or a total of 1 g has been administered.

PROMETHAZINE (PHENERGAN)

CLASS

Phenothiazine, antihistamine

DESCRIPTION

Promethazine is an H_1-receptor antagonist that blocks the actions of histamine by competitive antagonism at the H_1 receptor. In addition to antihistaminic effects, promethazine also possesses sedative, antimotion, antiemetic, and considerable anticholinergic activity. Promethazine often is administered with analgesics, particularly narcotics, to potentiate their effects, although the occurrence of potentiation is controversial.

ONSET AND DURATION

Onset: IV (rapid)
Duration: 4-6 hr

INDICATIONS

Nausea and vomiting
Motion sickness
Preoperative and postoperative, obstetrical (during labor) sedation
To potentiate the effects of analgesics
Allergic reactions

CONTRAINDICATIONS

Hypersensitivity
Comatose states
Central nervous system depression from alcohol, barbiturates, or narcotics
Signs associated with Reye's syndrome

ADVERSE REACTIONS

Sedation
Dizziness
May impair mental and physical ability
Allergic reactions
Dysrhythmias
Nausea and vomiting
Hyperexcitability
Dystonias
Use in children may cause hallucinations, convulsions, and sudden death

DRUG INTERACTIONS

Concomitant use of central nervous system depressants may have an additive sedative effect.
Increased incidence of extrapyramidal effects occurs when given with some MAO inhibitors.
Concomitant use of epinephrine may decrease blood pressure further.

HOW SUPPLIED

25, 50 mg/mL in 1-mL ampules and Tubex syringes

DOSAGE AND ADMINISTRATION

Adult: 12.5-25 mg IV (dilute in 9 mL of NaCl and give 25 mg or less over 10-15 min) or deep IM (undiluted)
Pediatric: Not indicated in the prehospital setting

SPECIAL CONSIDERATIONS

Pregnancy safety: Category C (generally considered safe for use during labor)
Use caution in patients with asthma, peptic ulcer, and bone marrow depression.
Take care to avoid accidental intraarterial injection. IM injections are the preferred route of administration. (Avoid veins in the hands or wrists.) Give slow IV administration over 1 min.

PROPRANOLOL (INDERAL)

CLASS

Beta-adrenergic blocker, antidysrhythmic (Class II)

DESCRIPTION

Propranolol is a nonselective beta-adrenergic blocker that inhibits chronotropic, inotropic, and vasodilator response to beta-adrenergic stimulation. It slows the sinus rate, depresses atrioventricular conduction, decreases cardiac output, and reduces blood pressure. In addition, propranolol decreases myocardial oxygen demand and reduces the risk of sudden death in patients with acute myocardial infarction.

ONSET AND DURATION

Onset: Within 1-2 hr
Duration: 6-12 hr

INDICATIONS

Hypertension
Angina pectoris
Ventricular tachycardia, ventricular fibrillation, and rapid supraventricular dysrhythmias refractory to other therapies
All patients with suspected MI and unstable angina in the absence of contraindications (can reduce the incidence of VF)
Useful as an adjunctive agent with fibrinolytic therapy (may reduce nonfatal reinfarction and recurrent ischemia)
To convert to normal sinus rhythm or to slow ventricular response (or both) in supraventricular tachydysrhythmias (reentry SVT, atrial fibrillation, or atrial flutter)
To reduce myocardial ischemia in AMI patients with elevated heart rate, blood pressure, or both

CONTRAINDICATIONS

Hemodynamically unstable patients
STEMI if signs of heart failure, low cardiac output, or increased risk for cardiogenic shock are present
Relative contraindications include P-R interval >0.24 sec, second- or third-degree heart block, active asthma, reactive airway disease, severe bradycardia, SBP <100 mm Hg

DRUG INTERACTIONS

Adverse reactions:
Bradycardia
Second- or third-degree atrioventricular block
Asthma
Cardiogenic shock
Pulmonary edema
Uncompensated congestive heart failure
Chronic obstructive pulmonary disease (relative)
Cocaine intoxication
Catecholamine-depleting drugs may potentiate hypotension.
Sympathomimetic effects may be antagonized.
Verapamil may worsen atrioventricular conduction abnormalities.
Succinylcholine effects may be enhanced.
Isoproterenol, norepinephrine, dopamine, and dobutamine may reverse effects of propranolol.
Epinephrine may cause a rise in blood pressure, a decrease in heart rate, and severe vasoconstriction.
Signs of hypoglycemia may be masked.

HOW SUPPLIED

1 mg/mL vials

DOSAGE AND ADMINISTRATION

Adult: 1-3 mg IV over 2-5 min (not to exceed 1 mg/min); can be repeated after 2 min (total dose of 0.1 mg/kg)
Pediatric: Not recommended.

SPECIAL CONSIDERATIONS

Pregnancy safety: Category C
Propranolol may produce life-threatening side effects; closely monitor patient during administration.
Use with caution in elderly patients.
Use with caution in patients with impaired hepatic or renal function.
Atropine should be readily available.

NOTE
Beta$_1$-selective drugs now available are used more commonly for cardiac emergencies.

RETEPLASE (RETAVASE)

CLASS

Fibrinolytic

DESCRIPTION

Reteplase is a recombinant plasminogen activator. Fibrinolytic action occurs by generating plasmin from plasminogen. Plasmin degrades the fibrin matrix of a thrombus. The drug is used in the management of acute myocardial infarction in adults, for the improvement of ventricular function following acute myocardial infarction, and for a reduction in the incidence of congestive heart failure. Treatment with reteplase should be initiated as soon as possible after the onset of acute myocardial infarction symptoms.

ONSET AND DURATION

Onset: Causes reperfusion within 90 min for most patients
Duration: Variable

INDICATIONS

Management of acute myocardial infarction in adults (must be confirmed with 12-lead ECG)

CONTRAINDICATIONS

Active internal bleeding
History of stroke
Recent intracranial or intraspinal surgery or trauma
Intracranial neoplasm, atrioventricular malformation, or aneurysm
Bleeding disorders
Severe uncontrolled hypertension

ADVERSE REACTIONS

Bleeding (internal and at superficial sites)
Reperfusion dysrhythmias
Allergic reaction (rare)
Nausea and vomiting
Hypotension

DRUG INTERACTIONS

Risk of bleeding will be increased if used concurrently with drugs that alter platelet function.
Risk of bleeding with concomitant use of heparin, vitamin K antagonist (e.g., warfarin) is greatly increased.
Reteplase is incompatible with heparin; do not administer in the same IV line.

HOW SUPPLIED

Supplied in kit with components for reconstitution: single-use reteplase vials (10.8 units each), single-use diluent vials of sterile water (10 mL each), sterile 10-mL syringes with 20-gauge needles, sterile dispensing pins, sterile 20-gauge needles for administration, and alcohol swabs. Reconstitute by withdrawing 10 mL of diluent; open the package containing the dispensing pin; remove the needle from the syringe and discard the needle; remove the connective cap from the dispensing pin and connect the syringe to the pin; remove the flip cap from one vial of reteplase; remove the protective cap from the spike end of the dispensing pin and insert the spike into the vial of reteplase; transfer the diluent through the dispensing pin into the vial of reteplase; with the dispensing pin and syringe still attached, swirl (not shake) the vial gently to dissolve the reteplase; withdraw 10 mL of the reconstituted solution back into the syringe; detach the syringe from the dispensing pin, and attach a sterile 20-gauge needle; the 10-mL bolus dose is now ready to administer.

DOSAGE AND ADMINISTRATION

Adult: Administered 10 units as IV bolus over 2 min; administer a second 10-unit IV bolus in 30 min. (Give NS flush before and after each bolus.) Heparin and aspirin should be administered concomitantly.
Pediatric: Safety not established

SPECIAL CONSIDERATIONS

Pregnancy safety: Category C
Reteplase should be given in an IV line in which no other medication is being injected or infused simultaneously.
Protect contents of package from light.

SODIUM BICARBONATE

CLASS

Buffer, alkalinizing agent, electrolyte supplement

DESCRIPTION

Sodium bicarbonate reacts with hydrogen ions to form water and carbon dioxide and thereby can act to buffer metabolic acidosis. As the plasma hydrogen ion concentration decreases, blood pH rises.

ONSET AND DURATION

Onset: 2-10 min
Duration: 30-60 min

INDICATIONS

Tricyclic antidepressant overdose
Known preexisting hyperkalemia
Known preexisting bicarbonate responsive acidosis
Intubated patient with continued long arrest interval, pulseless electrical activity
Alkalinization for treatment of specific intoxications/rhabdomyolysis
Management of metabolic acidosis
Diabetic ketoacidosis

CONTRAINDICATIONS

Not effective in hypercarbic acidosis (e.g., cardiac arrest and CPR without intubation)
In patients with chloride loss from vomiting and gastrointestinal suction
Metabolic and respiratory alkalosis
Severe pulmonary edema
Abdominal pain of unknown origin
Hypocalcemia
Hypokalemia
Hypernatremia
When administration of sodium could be detrimental

ADVERSE REACTIONS

Metabolic alkalosis
Hypoxia
Rise in intracellular P_{CO_2} and increased tissue acidosis
Electrolyte imbalance (hypernatremia)
Seizures
Tissue sloughing at injection site

DRUG INTERACTIONS

Sodium bicarbonate may precipitate in calcium solutions. Alkalinization of urine may shorten elimination half-lives of certain drugs.
Vasopressors may be deactivated.

HOW SUPPLIED

50 mEq in 50 mL; 0.5, 0.6 mEq/mL

DOSAGE AND ADMINISTRATION

Urgent Forms of Metabolic Acidosis/Severe Hyperkalemia
Adult: 1 mEq/kg IV
Pediatric: Same as adult; infuse slowly and only if ventilations are adequate

SPECIAL CONSIDERATIONS

Pregnancy safety: Category C
Not recommended for routine use in cardiac arrest patients.
When possible, blood gas analysis should guide bicarbonate administration.
Bicarbonate administration produces carbon dioxide, which crosses cell membranes more rapidly than bicarbonate (potentially worsening intracellular acidosis).
Sodium bicarbonate may increase edematous or sodium-retaining states.
Sodium bicarbonate may worsen congestive heart failure.
Maintain adequate ventilation (gas exchange).

SOTALOL (BETAPACE, SORINE)

CLASS

Beta blocker, Class III antidysrhythmic

DESCRIPTION

Sotalol is a nonselective beta-adrenergic blocking agent used to treat ventricular and supraventricular dysrhythmias in patients without structural heart disease. The drug has both type II (beta-blocking) and type III (cardiac action potential elongation) properties. Because of this, sotalol is used in the treatment of atrial dysrhythmias or life-threatening ventricular dysrhythmias, including sustained ventricular tachycardia. It should not be used for mild dysrhythmias because it is known to be proarrhythmic, with an increased risk for torsades de pointes. It should also be avoided in patients with poor perfusion because of its significant negative inotropic effects.

ONSET AND DURATION

Onset: Rapid
Duration: 8-16 hr

INDICATIONS

Ventricular and atrial dysrhythmias
SVTs in patients without structural heart disease

CONTRAINDICATIONS

Bronchial asthma
Sinus bradycardia
Second- and third-degree AV block (unless a functioning pacemaker is present)
Congenital or acquired long QT syndromes
Cardiogenic shock
Uncontrolled congestive heart failure
Hypersensitivity to sotalol

ADVERSE REACTIONS

Bradycardia
Heart blocks
Hypotension
QT prolongation
Syncope
Torsades de pointes
Ventricular dysrhythmias

DRUG INTERACTIONS

Most drug interactions with sotalol occur via enhanced pharmacological and electrophysiological effects (beta blockade, QT prolongation, AV blockade) with other drugs.
Proarrhythmic events are common. Use caution when administering sotalol together with calcium channel blockers such as verapamil and diltiazem because concomitant use may have additive effects on AV conduction, ventricular function, and blood pressure. Use caution when administering sotalol together with beta agonists such as albuterol, terbutaline, and isoproterenol.

HOW SUPPLIED

Tablet: 80, 120, 160, 240 mg
Solution for injection: 150 mg/10 mL

DOSAGE AND ADMINISTRATION (IV)

1-1.5 mg/kg; follow protocol for infusion rate

SPECIAL CONSIDERATIONS

Pregnancy safety: Category B
As with all beta blockers, sotalol may worsen congestive heart failure because of impaired ventricular contraction or decreased ejection fraction.
Doses should be reduced in patients with renal impairment.

STREPTOKINASE (STREPTASE)

CLASS

Fibrinolytic agent

DESCRIPTION

Streptokinase combines with plasminogen to produce an activator complex that converts free plasminogen to the proteolytic enzyme plasmin. The plasmin in turn functions as an enzyme that degrades fibrin threads and fibrinogen, causing lysis of the blood clot. Streptokinase is administered to selected patients with acute myocardial infarction.

ONSET AND DURATION

Onset: 10-20 min (fibrinolysis, 10-20 min; clot lysis, 60-90 min)
Duration: 3-4 hr (prolonged bleeding times up to 24 hr)

INDICATIONS

Acute myocardial infarction
Massive pulmonary emboli
Arterial thrombosis and embolism
To clear arteriovenous cannulae
Deep venous thrombosis (rare)

CONTRAINDICATIONS

Hypersensitivity
Active bleeding
Recent surgery (within 2-3 weeks)
Recent cerebrovascular accident
Prolonged cardiopulmonary resuscitation
Intracranial or intraspinal surgery
Recent significant trauma (particularly head trauma)
Uncontrolled hypertension (systolic pressure ≥180 mm Hg; diastolic pressure ≥110 mm Hg)

ADVERSE REACTIONS

Bleeding (gastrointestinal, genitourinary, intracranial, other sites)
Allergic reactions
Hypotension
Chest pain
Reperfusion dysrhythmias
Abdominal pain

DRUG INTERACTIONS

Acetylsalicylic acid may increase risk of bleeding (and may be beneficial in improving overall effectiveness).
Heparin and other anticoagulants may increase risk of bleeding and improve overall outcome.

HOW SUPPLIED

250,000, 750,000, and 1,500,000 unit vials
Reconstitute by slowly adding 5 mL of sodium chloride or D_5W, directing the stream toward the side of the vial, rather than into the powder. Gently roll—do not shake—the vial for reconstitution. Slowly dilute the entire contents of the vial to a total of 45 mL.

DOSAGE AND ADMINISTRATION

Acute Myocardial Infarction
Adult: 1.5 million units diluted to 45 mL (IV) over 1 hr (use infusion pump)
Pediatric: Safety not established

SPECIAL CONSIDERATIONS

Pregnancy safety: Category C
Do not administer IM injections to patients receiving fibrinolytic drugs.
Obtain blood sample for coagulation studies before administration.
Carefully monitor vital signs.
Observe the patient for bleeding.
Use caution when moving patient to avoid bruising or bleeding.
Do not draw arterial blood gas specimens in fibrinolytic therapy candidates.
Use one IV line exclusively for fibrinolytic administration.

SUCCINYLCHOLINE (ANECTINE)

CLASS

Neuromuscular blocker (depolarizing)

DESCRIPTION

Succinylcholine has the quickest onset and briefest duration of action of all neuromuscular blocking drugs, making it a drug of choice for procedures such as endotracheal intubation, electroconvulsive shock therapy, and terminating laryngospasm. Like nondepolarizing blockers, depolarizing drugs also bind to the receptors for acetylcholine. However, because they cause depolarization of the muscle membrane, they often lead to fasciculations and some muscular contractions.

ONSET AND DURATION

Onset: Less than 1 min
Duration: 5-10 min after single IV dose

INDICATIONS

To facilitate intubation
Terminating laryngospasm
Muscle relaxation

CONTRAINDICATIONS

Burns or injuries in the first 12 hr
Hypersensitivity
Skeletal muscle myopathies
Inability to control airway and/or support ventilations with oxygen and positive pressure
Personal or family history of malignant hyperthermia
Acute rhabdomyolysis
Intraocular (globe rupture) injuries

ADVERSE REACTIONS

Hypotension
Respiratory depression
Bradycardias
Dysrhythmias
Initial muscle fasciculation
Excessive salivation
Malignant hyperthermia
Allergic reaction
Succinylcholine may exacerbate hyperkalemia in trauma patients (hours after trauma).

DRUG INTERACTIONS

Oxytocin, beta blockers, chronic contraceptive use, and organophosphates may potentiate effects.
Diazepam may reduce duration of action.
Cardiac glycosides may induce dysrhythmias.

HOW SUPPLIED

20, 100 mg/mL; 1-g multidose vial

DOSAGE AND ADMINISTRATION

NOTE
If the patient is conscious, explain the effects of the medication before administration. Premedication with atropine should be strongly considered, particularly in the pediatric age group. Premedicating with lidocaine may blunt any increase in intracranial pressure associated with intubation. Finally, diazepam or another sedative should be used in any conscious patient before undergoing neuromuscular blockade.

Adult: 0.3-1.1 mg/kg (25-75 mg) over 10-30 sec IV; 0.04-0.07 mg/kg to maintain relaxation
Pediatric: 1-2 mg/kg dose rapid IV; max 150 mg
Rapid Sequence Intubation
1-1.5 mg/kg IV/IO for adults and children; 2 mg/kg IV/IO for infants

SPECIAL CONSIDERATIONS

Pregnancy safety: Category C

NOTE
Neuromuscular blocking agents will produce respiratory paralysis. Therefore intubation and ventilatory support must be readily available.

Carefully monitor the patient and be prepared to resuscitate. Administer with caution to patients with severe trauma, burns, and electrolyte imbalances (high potassium levels).
Brain or spinal cord injury may prolong effects.
Patients must have a patent or artificial airway and adequate sedation during paralysis. Children are not as sensitive to succinylcholine on a weight basis as adults and may require higher doses.
Succinylcholine has no effect on consciousness or pain.
Succinylcholine will not stop neuronal seizure activity.
Succinylcholine rarely may cause ventricular dysrhythmias/cardiac arrest in infants and children.

TENECTEPLASE (TNK-TPA)

CLASS

Fibrinolytic

DESCRIPTION

Tenecteplase is a modified form of human tissue plasminogen activator (tPA) that binds to fibrin and converts plasminogen to plasmin. The drug has been mass produced using recombinant DNA technology. The enzyme binds to fibrin-bound plasminogen at the site of an arterial clot, thus converting plasminogen to plasmin. Plasmin digests the fibrin strands of the clot, causing clot lysis and restoration of perfusion to the occluded artery. In prehospital care, fibrinolytic agents are used in treating selected patients with acute evolving myocardial infarction (STEMI).

INDICATIONS

AMI with ST-elevation (STEMI) attributable to coronary artery thrombosis

CONTRAINDICATIONS

Active bleeding or known bleeding disorder
Recent surgery (within 2-3 weeks)
Recent cerebrovascular accident
History of intracranial hemorrhage
Prolonged cardiopulmonary resuscitation
Recent intracranial or intraspinal surgery
Recent significant trauma (particularly head trauma)
Seizure at onset of stroke symptoms
Uncontrolled hypertension
Recent gastrointestinal bleeding

ADVERSE REACTIONS

Bleeding (gastrointestinal, genitourinary, intracranial, other sites)
Allergic reactions
Hypotension
Chest pain
Reperfusion dysrhythmias
Abdominal pain

DRUG INTERACTIONS

Use with caution in patients who have recently received glycoprotein IIb/IIIa inhibitors or anticoagulants (e.g., warfarin) because of the potential for enhanced effects on hemostasis.
Platelet aggregation may be impaired by serotonin norepinephrine reuptake inhibitors (SNRIs).

HOW SUPPLIED

50-mg powder for injection; reconstitute by using the diluent, syringe, needle, and dispensing system provided by the manufacturer. Reconstitute only with 10 mL of sterile water for injection without preservatives. Gently swirl the vial until contents are completely dissolved. Do not shake. The reconstituted vial will be a colorless to pale yellow transparent solution containing TNKase at 5 mg/mL.

DOSAGE AND ADMINISTRATION

Adult: IV bolus over 5 sec
Weight adjusted: <60 kg, give 30 mg; 60-69 kg, give 35 mg; 70-79 kg, give 40 mg; 80-89 kg, give 45 mg; ≥90 kg, give 50 mg
Pediatric: Not indicated

SPECIAL CONSIDERATIONS

Pregnancy safety: Category C
Incompatible with dextrose solutions.
Administer via a dedicated IV line in which no other medications are being simultaneously injected or infused.

TETRACAINE (PONTOCAINE)

CLASS

Topical ophthalmic anesthetic

DESCRIPTION

Tetracaine is used for rapid, brief superficial anesthesia. The agent inhibits conduction of nerve impulses from sensory nerves.

ONSET AND DURATION

Onset: Within 30 sec
Duration: 10-15 min

INDICATIONS

Short-term relief from eye pain or irritation
Patient comfort before eye irrigation

CONTRAINDICATIONS

Hypersensitivity to tetracaine
Open injury to the eye

ADVERSE REACTIONS

Burning or stinging sensation
Irritation

DRUG INTERACTIONS

Incompatible with mercury or silver salts often found in ophthalmic products

HOW SUPPLIED

0.5% solution

DOSAGE AND ADMINISTRATION

Adult: 1-2 drops
Pediatric: Same as adult

SPECIAL CONSIDERATIONS

Pregnancy safety: Category C
Tetracaine can cause epithelial damage and systemic toxicity.
Tetracaine is not recommended for prolonged use.

THIAMINE (BETAXIN)

CLASS

Vitamin (B_1)

DESCRIPTION

Thiamine combines with adenosine triphosphate to form thiamine pyrophosphate, a coenzyme necessary for carbohydrate metabolism. Most vitamins required by the body are obtained through diet; however, certain states such as alcoholism and malnourishment may affect the intake, absorption, and utilization of thiamine. The brain is extremely sensitive to thiamine deficiency.

ONSET AND DURATION

Onset: Rapid
Duration: Depends on the degree of deficiency

INDICATIONS

Coma of unknown origin (with administration of dextrose 50% or naloxone)
Delirium tremens

Beriberi (rare)
Wernicke's encephalopathy

CONTRAINDICATIONS

None significant

ADVERSE REACTIONS

Hypotension (from rapid injection or large dose)
Anxiety
Diaphoresis
Nausea and vomiting
Allergic reaction (usually from IV injection; rare); angioedema

DRUG INTERACTIONS

None significant

HOW SUPPLIED

1-, 2-mL vials (100 mg/mL)

DOSAGE AND ADMINISTRATION

Adult: 100 mg slow IV or IM
Pediatric: Not recommended in the prehospital setting

SPECIAL CONSIDERATIONS

Pregnancy safety: Category A (Category C if dose exceeds recommended daily allowance)
Large IV doses may cause respiratory difficulties.
Anaphylactic reactions have been reported.

TIROFIBAN (AGGRASTAT)

CLASS

Glycoprotein IIb/IIIa inhibitor

DESCRIPTION

Glycoprotein IIb/IIIa inhibitors inhibit the integrin GP IIb/IIIa receptor in the membrane of the platelets. As a result, they inhibit the common final pathway activation of platelet aggregation. Tirofiban (in combination with aspirin and heparin) is indicated for use in patients who have unstable angina or NSTEMI infarction.

ONSET AND DURATION

Onset: Within 30 min
Duration: Platelet aggregation restored within 4-8 hr after infusion is stopped

INDICATIONS

Patients with NSTEMI or unstable angina undergoing PCI

CONTRAINDICATIONS

Active internal bleeding
Bleeding disorder within the past 30 days
History of intracranial hemorrhage, neoplasm, AV malformation, aneurysm, or stroke within 30 days
Major surgical procedure or trauma within 1 month
Aortic dissection, pericarditis, and severe hypertension
Hypersensitivity to any GP IIb/IIIa inhibitor
Low platelet count

ADVERSE REACTIONS

Anaphylactoid reaction/anaphylactic shock
Bleeding (secondary to drug-induced platelet dysfunction)
GI bleeding
Hematemesis
Hematuria
Hypotension
Intracranial bleeding
Platelet dysfunction
Retroperitoneal bleeding
Stroke
Thrombocytopenia

DRUG INTERACTIONS

Concomitant use of other agents that may affect hemostasis, such as anticoagulants, other platelet inhibitors, NSAIDs, and thrombolytic agents, may be associated with an increased risk of bleeding.

HOW SUPPLIED

Premixed solution for injection: 50 mcg/mL

DOSAGE AND ADMINISTRATION (ADULT)

0.4 mcg/kg/min IV for 30 min; then 0.1 mcg/kg/min IV infusion over 18-24 hr after PCI

SPECIAL CONSIDERATIONS

Pregnancy safety: Category B
The 2004 ACCP guidelines recommend that tirofiban NOT be used in patients undergoing primary PCI.
Reduce dose in patients with impaired renal function.

VASOPRESSIN (PITRESSIN)

CLASS

Naturally occurring antidiuretic hormone

DESCRIPTION

Vasopressin acts by direct stimulation of smooth muscle V_1 receptors. When given in extremely high doses, it acts as a noradrenergic peripheral vasoconstrictor. Vasopressin may be used as an alternative pressor to epinephrine in adult shock-refractory VF; in asystole and PEA; and for hemodynamic support in septic shock.

ONSET AND DURATION

Onset: Immediate
Duration: Variable

INDICATIONS

As an alternative pressor to epinephrine in adult cardiac arrest
Vasodilatory shock

CONTRAINDICATIONS

Responsive patients with coronary artery disease

ADVERSE REACTIONS

Ischemic chest pain
Abdominal distress
Sweating
Nausea and vomiting
Tremors
Bronchial constriction
Uterine contraction

DRUG INTERACTIONS

No significant drug reactions have been reported.

HOW SUPPLIED

20 units/mL

DOSAGE AND ADMINISTRATION

Adult: Ventricular fibrillation/cardiac arrest: 40 units IV/IO push; may replace either first or second dose of epinephrine
Vasodilatory shock: Continuous infusion of 0.02-0.04 unit/min
Child and infant:
Cardiac arrest: 0.4-1 unit/kg IV/IO bolus (max 40 units)
Hypotension (continuous infusion): 0.0002-0.002 unit/kg/min (0.2-2 milliunits/kg/min)

SPECIAL CONSIDERATIONS

Pregnancy safety: Category C
Vasopressin may increase peripheral vascular resistance and provoke cardiac ischemia and angina.
Not recommended for responsive patients with coronary artery disease.

VECURONIUM

CLASS

Nondepolarizing neuromuscular blocker

DESCRIPTION

Vecuronium bromide is an intermediate-acting, nondepolarizing, neuromuscular blocking agent. Nondepolarizing agents produce skeletal muscle paralysis by blockade at the myoneural junction. Unlike depolarizing agents, vecuronium has little agonist activity, with no depolarizing effect at the motor endplate. Neuromuscular blockade progresses in a predictable order, beginning with muscles associated with fine movements (e.g., eyes, face, and neck); followed by muscles of the limbs, chest, and abdomen; and, finally, the diaphragm. Vecuronium is used to promote skeletal muscle relaxation during surgery, to aid controlled respiration by increasing pulmonary compliance, and to facilitate endotracheal intubation.

ONSET AND DURATION

Onset: Within 1 min
Duration: 25-40 min (dose related)

INDICATIONS

To facilitate intubation
Muscle relaxation

CONTRAINDICATIONS

Bromide hypersensitivity
Inability to control airway and/or support ventilations with oxygen and positive pressure
Bradycardias
Dysrhythmias
Hypotension
Respiratory depression
Muscular disease
Malignant hyperthermia

ADVERSE REACTIONS

Rare hypersensitivity reactions (e.g., bronchospasm, flushing, erythema, urticaria, hypotension, sinus tachycardia)
Excessive doses of vecuronium can cause prolonged apnea, dyspnea, respiratory depression, and/or profound muscular weakness (muscle paralysis).

DRUG INTERACTIONS

Can interact with opiate agonists by increasing the incidence and severity of bradycardia and hypotension.
Administration of IV phenytoin to patients currently receiving vecuronium has been noted to augment the neuromuscular activity of vecuronium.

HOW SUPPLIED

Powder for injection: 10, 20 mg

DOSAGE AND ADMINISTRATION

Neuromuscular Blockade
Adults, adolescents, and children >10 years: 80-100 mcg/kg IV; reconstitute by adding 10 or 20 mL of bacteriostatic water for injection to 10 or 20 mg, respectively, to give a parenteral solution containing 1 mg/mL
Rapid Sequence Intubation
0.1-02 mg/kg IV/IO for adults; 0.1-0.3 mg/kg IV/IO in children

SPECIAL CONSIDERATIONS

Pregnancy safety: Category C
Reconstituted vecuronium, which has an acid pH, should not be mixed with alkaline solutions (e.g., barbiturate solutions such as thiopental) in the same syringe or administered simultaneously during intravenous infusion through the same needle or through the same intravenous line.

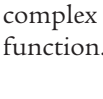
VERAPAMIL (ISOPTIN)

CLASS

Calcium channel blocker (Class IV antidysrhythmic)

DESCRIPTION

Verapamil is used as an antidysrhythmic, antianginal, and antihypertensive agent. It works by inhibiting the movement of calcium ions across cell membranes. The slow calcium ion current blocked by verapamil is more important for the activity of the sinoatrial node and atrioventricular node than for many other tissues in the heart. By interfering with this current, calcium channel blockers achieve some selectivity of action. Verapamil decreases atrial automaticity, reduces atrioventricular conduction velocity, and prolongs the atrioventricular nodal refractory period. In addition, verapamil depresses myocardial contractility, reduces vascular smooth muscle tone, and dilates coronary arteries and arterioles in normal and ischemic tissues. Verapamil may be used as an alternative drug (after adenosine) to terminate reentry SVT with narrow QRS complex and adequate blood pressure and preserved LF function.



NOTE

Some physicians recommend slow IV administration of 500 mg of calcium chloride before the dose of verapamil to minimize the untoward results of hypotension and bradycardia.

ONSET AND DURATION

Onset: 1-5 min
Duration: 30-60 min (may persist longer)

INDICATIONS

Give only to narrow-complex reentry supraventricular tachycardias or known supraventricular dysrhythmias.
Atrial flutter with a rapid ventricular response
Atrial fibrillation with a rapid ventricular response
Multifocal atrial tachycardia
Vasospastic and unstable angina

CONTRAINDICATIONS

Hypersensitivity
Sick sinus syndrome (unless the patient has a functioning pacemaker)
Second- or third-degree heart block
Sinus bradycardia
Hypotension
Cardiogenic shock
Severe congestive heart failure
Wolff-Parkinson-White syndrome with atrial fibrillation or flutter
Patients receiving IV beta blockers
Give with extreme caution to patients receiving oral beta blockers.
Wide-complex tachycardias of uncertain origin (ventricular tachycardia can deteriorate into ventricular fibrillation when calcium channel blockers are given.)

ADVERSE REACTIONS

Dizziness
Headache
Nausea and vomiting
Hypotension
Bradycardia
Complete atrioventricular block
Peripheral edema

DRUG INTERACTIONS

Verapamil increases serum concentration of digoxin.
Beta-adrenergic blockers may have additive negative inotropic and chronotropic effects.
Antihypertensives may potentiate hypotensive effects.

HOW SUPPLIED

Parenteral: 5 mg/2 mL in 2-, 4-, 5-mL vials, or 2-, 4-mL ampules

DOSAGE AND ADMINISTRATION

Adult:
- Initial dose: 2.5-5 mg slow IV bolus over 2 min (over 3 min in older patients)
- Repeat dose: 5-10 mg bolus in 15-30 min after initial dose if needed; or 5 mg bolus every 15 min until a desired response is achieved (max dose 30 mg)

Pediatric: Not recommended in the prehospital setting

SPECIAL CONSIDERATIONS

Pregnancy safety: Category C
Closely monitor patient's vital signs.
Be prepared to resuscitate.
Atrioventricular block or asystole may occur because of slowed atrioventricular conduction.

Glossary

abandonment Terminating medical care without legal excuse or turning care over to personnel who do not have training and expertise appropriate for the medical needs of the patient.

abdominal Pertaining to the abdomen.

abdominal aorta The portion of the descending aorta that passes from the aortic hiatus of the diaphragm into the abdomen, where it divides into the two common iliac arteries.

abdominal cavity The space within the abdominal walls between the diaphragm and the pelvic area; it contains the liver, stomach, intestines, spleen, kidneys, and associated tissues and vessels.

abdominopelvic cavity The space between the diaphragm and the groin.

abduction Movement away from the midline.

abnormal Deviating from the normal.

abnormal presentation A type of vaginal delivery in which the newborn's head does not deliver first.

abortion The spontaneous or induced termination of a pregnancy before the fetus has developed into a stage of viability.

abrasion A partial-thickness injury caused by scraping or rubbing away of a layer or layers of skin.

abruptio placentae Separation of the placenta implanted in a normal position in a pregnancy of 20 weeks or more; it occurs during labor or delivery of the fetus.

absence seizure A seizure that is characterized by brief lapses of consciousness without loss of posture; also known as *petit mal seizure*.

absolute refractory period The portion of the action potential during which the membrane is insensitive to all stimuli regardless of strength.

absorption The process by which drug molecules are moved from the site of entry into the body into the general circulation.

accelerated atrioventricular conduction See *anomalous conduction*.

accessory muscles Muscles that sometimes assist in breathing; includes the scalenes and the sternocleidomastoid (deep muscles of the neck and thorax), posterior neck and back muscles, and the abdominal muscles.

acclimatization Physical adjustment to a different climate or to changes in altitude or temperature.

acetabulum The large, cup-shaped articular cavity at the juncture of the ilium, the ischium, and the pubis that contains the ball-shaped head of the femur.

acetate A byproduct of fatty acids in the liver.

acetoacetic acid A colorless, oily ketone body produced by the metabolism of lipids and pyruvates; it is excreted in trace amounts in normal urine and in elevated amounts with diabetes mellitus, especially in ketoacidosis.

acetonemia The presence of acetone in the blood, characterized by the fruity breath odor of ketoacidosis.

acetylcholine A neurotransmitter, widely distributed in body tissues, with the primary function of mediating the synaptic activity of the nervous system.

acetylcholinesterase An enzyme found in the synaptic cleft that causes the breakdown of acetylcholine into acetic acid and choline, thereby limiting the stimulatory effect of acetylcholine.

acid A compound that yields hydrogen ions when dissociated in solution.

acid-base balance The body's balance between acidity and alkalinity.

acidosis A condition marked by a high concentration of hydrogen ions (i.e., a pH below 7.35).

acinus A small lobule of a compound gland; the exocrine portion of the pancreas that produces pancreatic juice.

acoustic neuroma A noncancerous tumor that involves the vestibular portion of the eighth (i.e., vestibulocochlear) cranial nerve.

acquired immunodeficiency syndrome A disease that results from infection with the human immunodeficiency virus; the syndrome impairs the immune system, giving rise to opportunistic infections and malignancies.

acquired immunity Immunity that develops after exposure to specific antigens; also known as *adaptive immunity*.

acromegaly A chronic metabolic condition characterized by a gradual, marked enlargement and elongation of the bones of the face, jaw, and extremities.

acromion process The lateral extension of the spine of the scapula; it provides attachment for the deltoideus and trapezius muscles.

actin A protein found in muscle fibers that acts with myosin to cause contraction and relaxation.

actinomycosis A chronic systemic disease characterized by deep, lumpy abscesses that extrude a granular pus through multiple sinuses.

action plan A plan of action based on the patient's condition and the environment.

action potential A change in membrane potential in an excitable tissue that acts as an electrical signal and is propagated in an all-or-none fashion.

active transport A carrier-mediated process that can move substances against a concentration gradient.

active tubular secretion Secretion that involves the transport of free drug from the blood across the proximal tubular cell and into the tubular urine by an active process against a concentration gradient.

acute chest syndrome A new abnormal consolidation on a chest radiograph in a patient with sickle cell disease.

acute dystonia A sudden impairment of muscle tone; it commonly involves the head, neck, or tongue and often occurs as an adverse effect of medication.

acute gastroenteritis Inflammation of the stomach and intestines with an associated sudden onset of vomiting, diarrhea, or both.

acute hepatitis An inflammatory condition of the liver associated with the sudden onset of malaise, weakness, anorexia, intermittent nausea and vomiting, and dull right upper quadrant pain, usually followed within 1 week by the onset of jaundice, dark urine, or both, characterized by jaundice.

acute mesenteric ischemia The abrupt interruption of intestinal blood flow; may result from an embolism, a thrombosis, or a low-flow state (decreased perfusion).

acute mountain sickness A common high-altitude illness that results when an unacclimatized person rapidly ascends to high altitudes.

acute pain Severe pain, such as that following trauma or accompanying myocardial infarction or other conditions and diseases.

acute prostatitis Inflammation of the prostate gland that develops suddenly.

acute psychosis A condition that refers to a patient who presents with one or more of the following criteria: a sudden onset of delusions that rapidly change; hallucinations; bizarre behavior and posture; or disorganized speech.

acute renal failure A clinical syndrome that results from a sudden and significant decrease in filtration through the glomeruli, leading to the accumulation of salt, water, and nitrogenous wastes within the body.

acute respiratory distress syndrome A fulminant form of respiratory failure characterized by acute lung inflammation and diffuse alveolar-capillary injury.

acute tubular necrosis A medical condition involving the death of tubular cells that form the tubule that transports urine to the ureters.

adaptation A cellular response to stress of any kind to escape and protect from injury; a central part of the response to changes in the physiological condition.

addiction A compulsive, uncontrollable dependence on a substance, habit, or practice to such a degree that cessation causes severe emotional, mental, or physiological reactions.

Addison's disease A rare and potentially life-threatening disorder caused by a deficiency of the corticosteroid hormones normally produced by the adrenal cortex.

adduction Movement toward the midline.

adenohypophysis The anterior lobe of the pituitary gland.

adenoma A tumor of glandular epithelium in which the cells of the tumor are arranged in a recognizable glandular structure.

adenosine A compound derived from nucleic acid and composed of adenine and a carbohydrate (i.e., sugar).

adenosine diphosphate A product of the hydrolysis of adenosine triphosphate.

adenosine monophosphate A compound that affects energy release in work done by muscles.

adenosine triphosphate Adenosine, an organic base, with three phosphate groups attached to it; it stores energy in muscles.

adhesion The quality of remaining in close contact with or stuck to another entity; also, a structure that joins several parts, sometimes abnormally.

adipose tissue A specialized connective tissue that stores lipids; also known as *fat tissue*.

adolescent A person 13 to 18 years of age.

adrenal gland Either of two secretory glands perched atop the kidneys; each gland consists of two parts, the cortex and medulla, which have independent functions.

adrenal medullary mechanism The mechanism by which epinephrine and norepinephrine are released from the adrenal medulla as a result of the same stimuli that increase sympathetic stimulation of the heart and blood vessels.

adrenaline An endogenous adrenal hormone that helps prepare the body for energetic action.

adrenergic Of or pertaining to the sympathetic nerve fibers of the autonomic nervous system, which use epinephrine or epinephrine-like substances as neurotransmitters.

adrenocorticotropic hormone A hormone of the anterior pituitary gland that stimulates growth of the adrenal gland cortex and secretion of corticosteroids.

adsorb To gather on a surface in a condensed layer.

adsorption The capacity of a substance to attract and hold other materials or particles on its surface.

adult respiratory distress syndrome A group of symptoms that accompany fulminant pulmonary edema, resulting in acute respiratory failure; also known as *noncardiogenic pulmonary edema*.

advanced cardiac life support Clinical care or guidelines for care of life-threatening cardiovascular and respiratory disorders.

advanced life support The provision of care that paramedics or allied health professionals render, including advanced airway management, defibrillation, intravenous therapy, and medication administration.

aerobic Of or pertaining to the presence of air or oxygen.

aerobic oxidation A biochemical reaction that increases the positive charges on an atom or the loss of negative charges in the presence of oxygen.

aerosol Pressurized gas that contains a finely nebulized medication for inhalation therapy.

affect An outward manifestation of a person's feelings or emotions.

affective disorder Any of a group of psychotic disorders characterized by severe and inappropriate emotional responses, prolonged and persistent disturbances of mood and related thought distortions, and other symptoms associated with depressed or manic states.

afferent division The division of the peripheral nervous system that transmits impulses from the periphery to the central nervous system.

afferent neurons Nerve fibers that send impulses from the periphery to the central nervous system.

affinity The propensity of a drug to bind or attach itself to a given receptor site.

afterdrop phenomenon A sudden return of cold blood and waste products to the core of the body as a result of rewarming methods used to treat hypothermia.

afterload The total resistance against which blood must be pumped. Also known as *peripheral vascular resistance*.

agglutinated Reference to cells that have clumped together. See *agglutination*.

agglutination A clumping together of cells as a result of their interaction with specific antibodies called agglutinins.

agglutinin A kind of antibody; its interaction with antigens is manifested as agglutination.

agitated delirium Describes a person with delirium who has (1) acute onset and fluctuating course, (2) reduced clarity of awareness of the environment, (3) perceptual disturbance, disorientation, or memory disturbance, and (4) underlying general medical condition.

agonal rhythm A ventricular escape complex or rhythm that occurs when the electrical impulses from the sinoatrial node, atria, or atrioventricular junction fail to reach the ventricles because of sinus arrest or high-degree atrioventricular block; frequently seen as the last rhythm in an unsuccessful resuscitation.

agonists Drugs that combine with receptors and initiate the expected response.

air embolism The presence of air bubbles in the bloodstream.

air trapping The result of a prolonged but inefficient expiratory effort, usually caused by chronic obstruction of the pulmonary tree, as is seen commonly in chronic obstructive pulmonary disease or asthma.

akathisia An abnormal condition characterized by restlessness and agitation.

albumin A water-soluble protein containing carbon, hydrogen, oxygen, nitrogen, and sulfur.

alcohol dependence A disorder characterized by chronic, excessive consumption of alcohol that results in injury to health or in inadequate social function and the development of withdrawal symptoms when the person stops drinking suddenly.

aldosterone A steroid hormone produced by the adrenal cortex to regulate the sodium and potassium balance in the blood.

aliquot A sample that is representative of the whole.

alkaline Having the reactions of an alkali.

alkalosis A condition marked by a low concentration of hydrogen ions (i.e., a pH above 7.45).

allergens Substances that can produce hypersensitivity reactions in the body.

allergic reaction A hypersensitivity response to an allergen to which a person previously was exposed and to which the person has developed antibodies.

allergy A hypersensitivity reaction to intrinsically harmless antigens, most of which are environmental.

allografting The transplantation of cells, tissues, or organs between nonidentical (genetically unrelated) persons.

all-or-none principle The principle that when a stimulus is applied to a cell, an action potential is produced or is not produced.

alpha cell A constituent of the islets of Langerhans that produces glucagon.

alpha-adrenergic receptor Any one of the postulated adrenergic components of receptor tissues that responds to norepinephrine and to various blocking agents.

alveolar duct Part of the respiratory passages beyond a respiratory bronchiole; alveolar sacs and alveoli arise from it.

alveoli Small outpouchings of walls of alveolar space through which gas exchange takes place between alveolar air and pulmonary capillary blood.

alveolus A small cavity; the terminal ending of a secretory gland. Alveoli of the lungs are microscopic, saclike dilations of terminal bronchioles.

Alzheimer's disease A disease characterized by confusion, memory failure, disorientation, speech disturbances, and inability to carry out purposeful movements.

amaurosis fugax Unilateral vision loss as a result of internal carotid artery plaque emboli.

ambulance A generic term that describes the various land-based emergency vehicles used by emergency medical services personnel, including basic and advanced life support units, paramedic units, mobile intensive care units, and others.

amenorrhea The absence of menstruation.

amino acid An organic chemical compound composed of one or more basic amino groups and one or more acidic carboxyl groups.

ammonia A colorless, aromatic gas consisting of nitrogen and hydrogen.

ammonium ion The monovalent cation NH_4.

amnestic Causing amnesia.

amniocentesis An obstetrical procedure in which a small amount of amniotic fluid is removed for laboratory analysis; it aids in diagnosis of fetal abnormalities.

amniotic fluid embolism An embolism that occurs when particulate matter in amniotic fluid forms an embolus and gains access to maternal circulation during labor or delivery or immediately after delivery.

amniotic sac A thin-walled bag that contains the fetus and amniotic fluid during pregnancy.

amplitude modulation A transmitted radio frequency carrier fixed in frequency but increasing or decreasing in amplitude in accordance with the strength of the applied audio.

ampulla A round, saclike dilation of the uterine tube.

amputation A complete or partial loss of a limb caused by mechanical force.
amylase A starch-splitting enzyme.
amyotrophic lateral sclerosis One of a group of rare disorders in which the nerves that control muscular activity degenerate in the brain and spinal cord; also called Lou Gehrig's disease.
anabolic steroid Any of several compounds derived from testosterone or prepared synthetically to promote general body growth, to oppose the effects of endogenous estrogen, or to promote masculinizing effects.
anaerobic Of or pertaining to the absence of oxygen.
anaerobic metabolism Metabolism that occurs in the absence of oxygen.
anal canal The final portion of the alimentary tract between the rectal ampulla and the anus.
anal fissure A linear ulceration or laceration of the skin of the anus.
anal fistula An abnormal opening of the cutaneous surface near the anus.
anal triangle The posterior portion of the perianal region through which the anal canal opens.
anaphylactic shock Shock that occurs when the body is exposed to a substance that produces a severe allergic reaction.
anaphylactoid reaction An allergic reaction that is not mediated by an antigen-antibody reaction; presents exactly like anaphylaxis, but does not require previous exposure.
anaphylaxis An exaggerated, life-threatening hypersensitivity reaction to a previously encountered antigen.
anasarca Generalized, massive edema.
anastomosis The joining of two parts.
anatomical dead space The volume of the conducting airways from the external environment down to the terminal bronchioles.
anatomical position A position standing erect with the feet and palms facing the examiner.
anchoring Attaching a high-angle rope to a secure point.
androgen Any steroid hormone that increases male characteristics.
anemia A decrease in blood hemoglobin level.
anesthesia Without sensation.
aneurysm A localized dilation of the wall of a blood vessel.
angina pectoris Ischemic chest pain most often caused by myocardial anoxia as a result of atherosclerosis of the coronary arteries.
angioedema A localized edematous reaction of the deep dermal or subcutaneous or submucosal tissues that appears as giant wheals.
angiogram A study of vessels.
angioplasty Repair of damaged vessels.
angiotensin I The inactive form of angiotensin, formulated by the stimulation of renin, which is converted to angiotensin II.
angiotensin II A potent vasoconstrictor that also acts to stimulate the secretion of antidiuretic hormone.
angiotensin-converting enzyme A circulating enzyme that participates in the body's renin-angiotensin system, which mediates extracellular volume and arterial vasoconstriction.
angle-closure glaucoma A form of glaucoma associated with a physically obstructed anterior chamber angle; may be chronic or, rarely, acute.
angle of Louis See *sternal angle.*
anhedonia The inability to enjoy what is usually pleasurable.
anion An ion with a negative charge.
anisocoria Normal or congenital unequal pupil size.
anomalous conduction A preexcitation syndrome; a clinical condition associated with abnormal conduction pathways between the atria and ventricles that bypass the atrioventricular node and bundle of His and allow the electrical impulses to initiate depolarization of the ventricles earlier than usual. Also known as *accelerated atrioventricular conduction*.
anorexia Lack or loss of appetite, resulting in an inability to eat.
anorexia nervosa A disorder characterized by a prolonged refusal to eat, resulting in emaciation, amenorrhea, emotional disturbance concerning body image, and an abnormal fear of becoming obese.
anovulation Failure of the ovaries to produce, mature, or release eggs.
antagonism The opposition between two or more medications; it occurs when the combined (conjoint) effect of two drugs is less than the sum of the drugs acting separately.
antagonist muscle A muscle that works in opposition to another muscle.
antagonists Agents designed to inhibit or counteract the effects of other drugs or undesired effects caused by normal or hyperactive physiological mechanisms.
antecubital fossa See *antecubital space.*
antecubital space The depressed area in front of the elbow or at the bend of the elbow; also known as the *antecubital fossa*.
antegrade amnesia The loss of memory for events that occurred immediately after recovery of consciousness.
antenatal Occurring or formed before birth.
antepartum The period before labor and delivery.
anterior The front, or ventral, surface.
anterior chamber of the eye The chamber of the eye between the cornea and the iris.
anterior communicating artery The artery that connects with the anterior cerebral arteries and completes the circle of Willis.
anterior cord syndrome A spinal cord injury usually seen in flexion injuries; caused by pressure on the anterior aspect of the spinal cord by a ruptured intervertebral disk or fragments of the vertebral body extruded posteriorly into the spinal canal.
anterior superior iliac spine One of two bony segments that form the iliac crest.

anthrax An acute infectious disease caused by the spore-forming bacterium *Bacillus anthracis*.

antibodies Substances produced by the body that destroy or inactivate a specific substance (antigen) that has entered the body.

anticholinergic Of or pertaining to the blocking of acetylcholine receptors, resulting in inhibition of transmission of parasympathetic nerve impulses.

anticoagulant A substance that prevents or delays coagulation of the blood.

antidiuretic hormone A hormone produced in the posterior pituitary gland to regulate the balance of water in the body by accelerating the resorption of water.

antidote A drug or other substance that opposes the action of a poison.

antigen-antibody reaction The binding of an antibody with an antigen of the type that stimulated the formation of the antibody; results in greater susceptibility for ingestion and destruction by phagocytes, or neutralization of an exotoxin.

antigenic site A site capable of binding to and reacting with an antibody.

antigens Substances (usually proteins) that cause the formation of an antibody and react specifically with that antibody.

antiplatelet drug A drug that interferes with platelet aggregation.

antipyretic Something that works against fever.

antivenin A suspension of venom-neutralizing antibodies prepared from the serum of immunized horses.

anuria The inability to urinate; the cessation of urine production; a diminished urinary output of less than 100 to 250 mL per day.

anus The distal end or outlet of the rectum.

anxiety A state or feeling of apprehension, uneasiness, agitation, uncertainty, and fear resulting from the anticipation of some threat or danger.

aorta The main and largest artery in the body.

aortic aneurysm A localized dilation of the wall of the aorta.

aortic body Any of the specialized nerve cells located in the arch of the aorta, where they monitor levels of oxygen and hydrogen ions in the cardiovascular system.

aortic semilunar valve A valve that guards the orifice between the left ventricle and the aorta.

apex of the heart The top or tip of the heart opposite the base.

Apgar score The evaluation of a newborn's physical condition, usually performed at 1 minute and 5 minutes after birth, including heart rate, respiratory effort, muscle tone, reflex irritability, and color.

aphasia Loss of the power of speech.

apical impulse A pulsation of the left ventricle of the heart, palpable and sometimes visible at the fifth intercostal space to the left of the midline.

apnea An absence of spontaneous respirations.

apneustic center A group of neurons in the pons that has a stimulatory effect on the inspiratory center.

apocrine gland A gland that has cells that contribute cytoplasm to its secretion, such as a mammary gland.

apothecary A system of graduated liquid volumes arranged in order of heaviness; it is based on the grain.

apparatus A vehicle used for fire suppression or rescue that does not include staff vehicles.

appendectomy Surgical removal of the appendix.

appendicitis An acute inflammation of the appendix.

appendicular region The limbs or extremities.

appendicular skeleton The bones of the upper and lower extremities.

appendix A wormlike, blunt process extending from the cecum; also known as the *vermiform appendix*.

application of principle A component of critical thinking in which the examiner makes patient care decisions based on conceptual understanding of the situation and the interpretation of data gathered from the patient.

aqueous humor The clear, watery fluid circulating in the anterior and posterior chambers of the eye.

Arachnida A large class of arthropods that includes spiders, scorpions, mites, and ticks.

arachnoid layer A delicate, weblike middle membrane that covers the brain.

areflexia A neurological condition characterized by the absence of reflexes.

areola The circular, pigmented area surrounding the nipple.

areolar connective tissue A loose tissue that consists of delicate webs of fibers and a variety of cells embedded in a matrix of soft, sticky gel.

areolar gland A gland that forms small, rounded projections from the surface of the areola of the mamma.

arrector pili Smooth muscles of the skin attached to hair follicles; when contraction occurs, the hair rises, resulting in gooseflesh.

arterial capillary The ends of capillaries closest to arterioles.

arteriogram A study of arteries.

arteriole A small branch of an artery.

arteriovenous anastomosis A vessel that allows blood to flow from arteries to veins without passing through capillaries; also known as an *arteriovenous shunt*.

arteriovenous fistula An internal anastomosis between an artery and a vein.

arteriovenous graft A synthetic material grafted between the patient's artery and vein.

arteriovenous malformation An abnormal connection between veins and arteries; believed to arise during fetal development or soon after birth.

arteriovenous shunt See *arteriovenous anastomosis*.

artery A vessel that carries blood away from the heart.

arthritis An inflammatory condition of the joints, characterized by pain and swelling.

arthroscopy Surgical inspection of a joint.

artifact A deflection on the electrocardiogram display or tracing produced by factors other than the electrical activity of the heart.

arytenoid cartilages Small, pyramidal laryngeal cartilages that articulate with the cricoid cartilage.

asbestosis A chronic lung disease caused by the inhalation of asbestos fibers; it results in the development of alveolar, interstitial, and pleural fibrosis.

ascending colon The segment of the colon that extends from the cecum in the right lower quadrant of the abdomen to the transverse colon at the hepatic flexure on the right side; usually at the level of the umbilicus.

ascites An abnormal intraperitoneal accumulation of fluid containing large amounts of protein and electrolytes.

aseptic Sterile, without germs.

asphyxiation A state of suffocation, caused by severe hypoxia, that leads to hypoxemia and hypercapnia, loss of consciousness, and, if not corrected, death.

aspiration Inhalation of foreign substances into the pulmonary system.

aspiration pneumonia Inflammation of the lung tissue from foreign material that enters the tracheobronchial tree.

asplenia Congenital absence or surgical removal of the spleen.

assault Creating apprehension, or unauthorized handling and treatment of a patient.

asthma A respiratory disorder characterized by recurring episodes of paroxysmal dyspnea, wheezing on expiration caused by constriction of the bronchi, coughing, and viscous mucoid bronchial secretions.

asthma exacerbation An aggravation of asthma, usually associated with severe symptoms.

astigmatism An abnormal condition of the eye in which the light rays cannot be focused clearly on a point on the retina because the spherical curve of the cornea is not equal in all meridians.

astrocyte gliosis A tumor composed of glial cells within the nervous system; it may be associated with respiratory center dysfunction and neuroepithelial bodies in the tracheobronchial tree, along with distal atelectasis.

asystole A life-threatening cardiac condition characterized by the absence of electrical and mechanical activity of the heart.

ataxia Failure of muscle coordination.

ataxic breathing A type of cluster or irregular breathing pattern characterized by a series of inspirations and expirations.

atelectasis An abnormal condition characterized by the collapse of lung tissue, which prevents the respiratory exchange of oxygen and carbon dioxide.

atelectatic breathing A modified respiratory effort thought to be a protective reflex to hyperinflate the lungs and reexpand alveoli that might have been collapsed.

atheroma An abnormal accumulation of fat or lipids as a cyst or a deposit in an arterial wall; a hard, atherosclerotic plaque.

atherosclerosis A common arterial disorder characterized by yellowish plaques of cholesterol, lipids, and cellular debris in the inner layers of the walls of large and medium-sized arteries.

athetosis A neuromuscular condition characterized by slow, continuous, and involuntary movement of the extremities.

atlantooccipital joint One of a pair of condyloid joints formed by the articulation of the atlas of the vertebral column with the occipital bone of the skull.

atlas The first cervical vertebra, which articulates with the occipital bone and the axis.

atmospheric pressure The pressure exerted by the weight of the atmosphere; at sea level this pressure is 760 mm Hg.

atom The smallest division of an element that exhibits all the properties and characteristics of the element; atoms consist of neutrons, electrons, and protons.

atonic seizure A seizure that produces an abrupt loss of muscle tone, loss of posture, or sudden collapse ("drop attacks").

atony Weak muscle tone.

atria Chambers or cavities, such as the atria of the heart.

atrial natriuretic factor A peptide released from the atria when atrial blood pressure is increased; it lowers blood pressure by increasing urine production, thus reducing blood volume.

atrial natriuretic hormone A hormone secreted by specialized muscle fibers in the atrial wall of the heart that influences water reabsorption in the kidney; it acts as an antagonist of aldosterone.

atrial synchronous ventricular pacemaker An artificial pacemaker synchronized with the patient's atrial rhythm; it paces the ventricles only when an atrioventricular block occurs.

atrial-ventricular demand pacemaker An artificial pacemaker that paces the atria or ventricles when the intrinsic rate of the paced chamber drops dangerously low.

atrioventricular canal The path through which the atria open into the ventricles.

atrioventricular dissociation A conduction disturbance in which atrial and ventricular contractions occur rhythmically but are unrelated to each other.

atrioventricular node An area of specialized cardiac muscle that receives the cardiac impulse from the sinoatrial node and conducts it to the bundle of His.

atrioventricular sequential pacemaker An artificial pacemaker that paces the atria first and then the ventricles when spontaneous activity is absent or slowed in the atria and ventricles.

atrioventricular valve A valve in the heart through which blood flows from the atria to the ventricles.

atrophy Decrease in size (shrinkage) of a cell, which adversely affects cell function.

attachments Physical and emotional bonds that develop between infants and their family members or caregivers.

attention deficit disorder A syndrome that affects children, adolescents, and, in rare cases, adults and is characterized by learning and behavioral disabilities.

auditory Of or pertaining to hearing or the organs of hearing.

auditory meatus A tubelike channel of the external ear extending from the auricle to the tympanum of the middle ear.

auditory ossicles The incus, malleus, and stapes; small bones in the middle ear that articulate with each other and the tympanic membrane.

auditory tube The auditory canal; it extends from the middle ear to the nasopharynx; also known as the *eustachian tube*.

aura A sensation that may precede a migraine or seizure activity.

auricle The part of the external ear that protrudes from the head; also known as the *pinna*.

auscultation A technique that requires the use of a stethoscope and is used to assess body sounds produced by the movement of various fluids or gases in organs or tissues.

autism spectrum disorder A range of neurodevelopmental disorders characterized by three sets of behavioral features: (1) impairment in social interaction, (2) communication deficits (both verbal and nonverbal), and (3) restricted, repetitive behaviors, including decreased imaginative play, stereotyped behaviors, and inflexible adherence to routines.

autoimmune disease A condition that occurs when the immune system mistakenly attacks and destroys healthy body tissue.

autoimmune pericarditis Inflammation of the pericardium associated with the production of antibodies directed against one's own tissues.

autoimmunity An abnormal characteristic or condition in which the body reacts against constituents of its own tissues.

autolysis The spontaneous disintegration of tissues or cells by the action of their own autogenous enzymes.

autonomic hyperreflexia Overactivity of the autonomic nervous system that causes an abrupt onset of extremely high blood pressure.

autonomic nervous system The division of the peripheral nervous system that acts as a control system functioning largely below the level of consciousness, and controls visceral functions.

automatic external defibrillator A device used in cardiac arrest to perform a computer analysis of the patient's cardiac rhythm and deliver defibrillatory shocks when indicated.

automatic implantable cardioverter-defibrillator A surgically implanted device that monitors a person's heart rate; it is designed to deliver defibrillatory shocks as needed.

automatic vehicle location A radio communications subsystem that uses one or more electronic methods periodically to determine the position of a land, marine, or air vehicle and relay that information via radio to a communications center.

automaticity A property of specialized excitable tissue that allows self-activation through spontaneous development of an action potential.

automatism Abnormal repetitive motor behavior such as lip smacking, chewing, or swallowing during which the patient is amnestic.

autonomic hyperreflexia syndrome A neurological disorder characterized by a discharge of sympathetic nervous system impulses as a result of stimulation of the bladder, large intestine, or other visceral organs.

autonomic nervous system The part of the nervous system that regulates involuntary vital functions, including the activity of cardiac muscle, smooth muscle, and glands.

autophagia Nutrition of the body by consumption of its own tissues.

avascular The absence of blood vessels.

Avogadro's number The number of molecules in a gram mole of any chemical substance.

avoidance The act of keeping away from someone, something, or a situation, or of preventing the occurrence of something; it requires the paramedic to continually be aware of the scene by being observant and knowledgeable about warning signs that may indicate a dangerous situation.

avulsion A full-thickness skin loss in which the wound edges cannot be approximated.

axial loading Vertical compression of the spine that results when direct forces are transmitted along the length of the spinal column.

axial region The head, neck, thorax, abdomen, and pelvis.

axial skeleton The bones of the head, neck, and torso.

axillae Armpits.

axillary node One of the lymph glands of the axillae that help fight infections in the chest, armpit, neck, and arm and drain lymph nodes from those areas.

axis The second cervical vertebra about which the atlas rotates, allowing the head to be turned, extended, or flexed.

axon The main central process of a neuron that normally conducts action potentials away from the neuron cell body.

azotemia The retention of excessive amounts of nitrogenous compounds in the blood.

B lymphocytes The lymphocytes responsible for antibody-mediated immunity.

Babinski's sign A reflex movement in which the great toe bends upward when the outer edge of the sole is scratched; also known as *Babinski's reflex*.

bacteremia The presence of bacteria in the blood.

bacteria Single-celled microorganisms that cause an infection characteristic of that species.

bacterial endocarditis Inflammation of the endocardium and one or more heart valves; also known as *infective endocarditis*.

bacterial meningitis A life-threatening illness that results from bacterial infection of the meninges.
bacterial pneumonia A type of pneumonia associated with a bacterial infection.
bacterial tracheitis A bacterial infection of the upper airway and subglottic trachea.
bacteriocidal Destructive to bacteria.
bacteriophage Any virus that causes lysis of host bacteria.
bacteriostatic Tending to restrain the development or the reproduction of bacteria.
ball-and-socket joint A joint that consists of a ball (head) at the end of one bone and a socket in an adjacent bone into which a portion of the ball fits.
bariatrics The field of medicine that focuses on the treatment and control of obesity and diseases associated with obesity.
baroreceptor A sensory nerve ending in the walls of the atria of the heart, venae cavae, aortic arch, and carotid sinuses; it is sensitive to stretching of the walls caused by an increase in blood pressure.
barotitis An inflammation of the ear caused by changes in atmospheric pressure.
barotrauma A physical injury sustained as a result of exposure to increased environmental pressure.
Bartholin's abscess The accumulation of pus that forms a lump in one of the Bartholin's glands; results from the duct of the gland being blocked, thereby allowing infection to occur.
Bartholin's gland One of two small, mucus-secreting glands located on the posterior and lateral aspect of the vestibule of the vagina.
Barton's bandage A circumferential head dressing applied to restrict jaw movement and minimize pain.
base A chemical compound that combines with an acid to form a salt; also known as an *alkali*.
base of the heart The portion of the heart opposite the apex, directed to the right side of the body.
base station A grouping of radio equipment consisting of at least a transmitter, a receiver, a transmission line, and an antenna located at a specific, fixed location.
basic life support Care provided by persons trained in first aid, cardiopulmonary resuscitation, and other noninvasive care.
basilar artery The single arterial trunk formed by the junction of the two vertebral arteries at the base of the skull.
basilar fracture A fracture that may occur when the mandibular condyles perforate the base of the skull but that more commonly results from extension of a linear fracture into the floor of the anterior and middle fossae.
basophil A white blood cell that promotes inflammation.
battering A form of domestic violence that establishes control and fear in a relationship through violence and other forms of abuse.
battery Physical contact with a person without consent and without legal justification.
Battle's sign Ecchymosis over the mastoid process caused by a fracture of the temporal bone.
Beck's triad A combination of three symptoms that characterize cardiac tamponade: elevated central venous pressure, muffled heart sounds, and hypotension.
behavior indicator Nonspecific behavioral changes that may suggest that a child is being maltreated. Behavior indicators for sexual abuse are called nonspecific because children may display such behavior changes because of other traumatic conditions. Prompt evaluation is warranted when these nonspecific behavior indicators occur to rule out maltreatment; appropriate assistance for the child must be obtained.
behavioral emergency A change in mood or behavior that cannot be tolerated by the involved person or others and requires immediate attention.
belay Method of attaching a safety rope and controlling the rope so that if the person or load starts to fall, the belay rope will prevent the fall.
Bell's palsy A condition in which paralysis of the facial muscles is caused by inflammation of the seventh cranial nerve (i.e., facial nerve); usually is one-sided and temporary and often develops suddenly.
benign A noncancerous tumor or harmless condition.
beta cell A constituent of the islets of Langerhans that produces insulin.
beta-adrenergic receptor Any of the postulated adrenergic components of receptor tissues that respond to epinephrine and various blocking agents.
beta-hydroxybutyric acid One of the ketone bodies that occur in abnormal amounts in diabetic ketoacidosis as a result of fatty acid oxidation.
bicarbonate buffer system The principal mechanism for stabilizing acid-base balance.
biceps brachii The biceps muscle of the arm that flexes and supinates the forearm.
bicuspid valve One of the two atrioventricular valves located between the left atrium and ventricle; also known as the *mitral valve*.
bifurcate To divide into two branches.
bilateral Having or occurring on two sides.
bile A bitter, yellow-green secretion of the liver that is stored in the gallbladder.
bilirubin The orange-yellow pigment of bile, formed principally from the breakdown of hemoglobin in red blood cells after termination of their normal life span.
bioethics The systematic study of moral dimensions including moral vision, decisions, conduct, and policies of the life sciences and health care.
biological disturbances Mental disorders that result from a physical rather than a purely psychological cause.
biological half-life The time required to metabolize or eliminate half the total amount of a drug in the body.
biology The study of life.
biosynthesis A chemical reaction that continually occurs throughout the body in which molecules form more complex molecules.

Biot's respiration A respiratory pattern consisting of irregular respirations that vary in depth and that are interrupted by intervals of apnea.

bioterrorism The use of biological agents, such as pathogenic organisms or agricultural pests, for the express purpose of causing death or disease, to instill a sense of fear and panic in the victims, and to intimidate governments or societies for political, financial, or ideological gain.

biotransformation The process by which a drug is converted chemically to a metabolite.

biphasic complex A QRS complex that is partly positive and partly negative.

biphasic positive airway pressure Airway support that combines partial ventilatory support and continuous positive airway pressure; allows the pressure to vary during each breath cycle

biphasic reaction An anaphylactic reaction that resolves and then recurs hours later without further exposure to the trigger.

bipolar disorder A disorder marked by alternating periods of mania and depression; also known as *manic-depressive disorder*.

bipolar lead A lead composed of two electrodes of opposite polarity.

bivalent cation An ion with two positive charges.

blast injury A general term used to describe damage to a person exposed to a pressure field.

blastocyst The stage of mammalian embryos in which the embryo consists of the inner cell mass and a thin trophoblast layer.

bleb An accumulation of fluid under the skin.

blood The fluid and its suspended, formed elements that circulate through the heart, arteries, capillaries, and veins.

blood clot The end result of the clotting process in blood; a blood clot normally consists of red cells, white cells, and platelets enmeshed in an insoluble fibrin network.

blood colloid osmotic pressure Osmotic pressure caused by the presence of plasma proteins (mostly albumin) that are too large to pass through the wall of the capillary; also known as *oncotic pressure*.

blood-brain barrier An anatomical-physiological feature of the brain thought to consist of walls of capillaries in the central nervous system and surrounding glial membranes; its function is to prevent or slow the passage of chemical compounds from the blood into the central nervous system.

blowout fracture A fracture of the floor of the orbit caused by a blow that suddenly increases the intraocular pressure.

blunt trauma An injury produced by the wounding forces of compression and change of speed, both of which can disrupt tissue.

B-NICE An acronym used for identifying five categories of weapons of mass destruction: *B*iological, *N*uclear, *I*ncendiary, *C*hemical, and *E*xplosives.

body The largest or main part of any organ or structure.

body lice Tiny parasites that concentrate around the waist, shoulders, axillae, and neck.

Bohr effect A property of hemoglobin; it states that an increasing concentration of protons and/or carbon dioxide will reduce the oxygen affinity of hemoglobin.

bone A highly specialized form of hard, connective tissue; it consists of living cells and mineralized matrix.

bone marrow Specialized soft tissue that fills the spaces in the cancellous bone of the epiphyses.

bone spurs Bony growths formed on normal bone.

bone tumor An abnormal growth of cells within a bone; may be malignant or benign.

bony labyrinth Part of the inner ear; it contains the membranous labyrinth.

borderline personality disorder A pervasive pattern of instability of interpersonal relationships, self-image, and affect, in addition to considerable impulsivity that begins by early adulthood.

botulism An often fatal form of food poisoning caused by the bacillus *Clostridium botulinum*.

bowel obstruction An occlusion of the intestinal lumen that results in blockage of normal flow of intestinal contents.

Bowman's capsule The expanded beginning of a renal tubule.

boxer's fracture Fracture of the fifth metacarpal bone from direct trauma to a closed fist.

Boyle's law See *general gas law*.

brachial plexus A network of nerves in the neck that passes under the clavicle and into the axilla, originating in the fifth, sixth, seventh, and eighth cervical nerves and the first two thoracic spinal nerves; the brachial plexus innervates the muscles and the skin of the chest, shoulders, and arms.

bradycardia A heart rate of less than 60 beats per minute.

bradykinin A peptide of nonprotein origin that contains nine amino acid residues; a potent vasodilator.

bradypnea A persistent respiratory rate slower than 12 breaths per minute.

brain abscess An accumulation of purulent material (pus) surrounded by a capsule within the brain.

brain tumor A mass in the cranial cavity.

brainstem The midbrain, pons, and medulla.

brand name See *trade name*.

Braxton-Hicks contraction Irregular tightening of the pregnant uterus that begins in the first trimester and increases in frequency, duration, and intensity as pregnancy progresses.

breech presentation The intrauterine position of the fetus in which the buttocks or feet present.

broad ligament A folded sheet of peritoneum draped over the uterine tubes, uterus, and ovaries.

bronchial breath sounds Breath sounds heard only over the trachea and are the highest in pitch.

bronchial tree An anatomical complex of the bronchi and bronchial tubes.

bronchiectasis An abnormal dilation of the bronchi caused by a pus-producing infection of the bronchial wall.

bronchiole A small branch of a bronchus.

bronchiolitis An acute viral infection of the lower respiratory tract that occurs primarily in infants under 18 months of age; it is characterized by expiratory wheezes, respiratory distress, inflammation, and obstruction at the level of the bronchioles.

bronchopulmonary dysplasia A chronic respiratory disorder characterized by scarring of lung tissue, thickened pulmonary arterial walls, and ventilation-perfusion mismatch; often occurs in infants who have dependence on long-term artificial ventilation.

bronchovesicular breath sounds Normal breath sounds heard over the major bronchi and over the upper right posterior lung field.

brow presentation See *face presentation*.

Brown-Séquard syndrome A hemitransection of the spinal cord. In the classic presentation, pressure on half of the spinal cord results in weakness of the upper and lower extremities on the ipsilateral (same) side and loss of pain and temperature sensation on the contralateral (opposite) side.

bruit An abnormal sound or murmur heard while auscultating an artery, organ, or gland.

buccal Of or pertaining to the inside of the cheek.

buccal route A route for administering medication in which the agent is placed between the teeth and mucous membrane of the cheek.

bulbourethral glands Small glands located just below the prostate gland that lubricate the terminal portion of the urethra and contribute to seminal fluid; also known as *Cowper's glands*.

bulimia nervosa A disorder characterized by an insatiable craving for food, often resulting in episodes of binge eating followed by purging (through self-induced vomiting or use of laxatives), depression, and self-deprivation.

bullae Thin-walled blisters of the skin or mucous membranes that contain clear, serous fluid.

bullet tumble See *bullet yaw*.

bullet yaw The forward rotation of a bullet around its center of mass, which causes an end-over-end motion, producing a greater energy exchange and greater tissue damage; also known as *bullet tumble*.

bundle of His A band of fibers in the myocardium through which the cardiac impulse is transmitted from the atrioventricular node to the ventricles.

bundle of Kent Fibers that connect atrial muscle to ventricular muscle, bypassing the AV node; also known as *Kent fibers*.

burette An intravenous device used to deliver a wide range of accurate, specific volumes.

bursa A small sac containing synovial fluid that helps ease friction between a tendon and skin or between a tendon and bone.

bursitis An inflammation of the bursa, the connective tissue structure surrounding a joint.

***C. diff* colitis** Inflammation of the colon caused by the bacterium *Clostridium difficile*.

calcaneus The heel bone, the largest of the tarsal bones.

calcium The fifth most abundant element in the human body; it occurs mainly in bone.

calipers An instrument with two hinged, adjustable legs used to measure components of the electrocardiogram.

canaliculus A very small tube or channel.

cancellous bone Latticelike tissue normally present in the interior of many bones where spaces usually are filled with marrow; also known as *spongy bone*.

cancer A neoplasm characterized by the uncontrolled growth of anaplastic cells that tend to invade surrounding tissue and to metastasize to distant body sites.

Candida A genus of yeastlike fungi.

candidiasis An infection caused by a species of *Candida* organisms that is characterized by pruritus, exudate, and easy bleeding.

cannulation The insertion of a cannula into a body duct or cavity.

capillaries Tiny vessels that connect arterioles to venules.

capillary network A complex, interconnected structure where a single blood cell traveling from an arteriole to a venule via a capillary bed passes through capillary segments.

capillary refill test A test used to evaluate the rate of blood flow through peripheral capillary beds.

capitation A method of payment to cover all health care expenses for each member of a managed care organization.

capitulum The lateral aspect of the humerus; it articulates with the head of the radius.

capnography The measurement of carbon dioxide concentrations in exhaled air.

capsid A protein coat that encloses a virus.

carbaminohemoglobin A chemical complex formed by carbon dioxide and hemoglobin after the release of oxygen by the hemoglobin to a tissue cell.

carbohydrate Any group of organic compounds composed of carbon, hydrogen, and oxygen; it is primarily obtained from plant foods.

carbonic acid An aqueous solution of carbon dioxide.

carbonic anhydrase The enzyme that converts carbon dioxide into carbonic acid.

carboxyhemoglobin A compound produced by the exposure of hemoglobin to carbon monoxide.

carcinogenic Cancer causing.

cardiac cycle The complete round of cardiac systole and diastole.

cardiac ejection fraction The percentage of ventricular blood volume released during a contraction.

cardiac muscle A special striated muscle of the myocardium that contains dark, intercalated disks at the junctions of the abutting fibers; cardiac muscle is characterized by special contractile abilities.

cardiac myopathy An abnormal condition of the heart characterized by weakness of the myocardium.
cardiac output The volume of blood pumped each minute by the left ventricle.
cardiac plexus One of several nerve complexes situated close to the arch of the aorta.
cardiac sphincter A ring of muscle fibers at the juncture of the esophagus and stomach.
cardiogenic shock Shock that results when cardiac action is unable to deliver sufficient circulating blood volume for tissue perfusion.
cardiography Recording the movements of the heart.
cardiomyopathy Any disease that affects the myocardium.
cardiopulmonary Of or pertaining to the heart and lungs.
cardiopulmonary resuscitation An emergency procedure for life support consisting of artificial respiration and manual external cardiac massage.
carina of the trachea A downward and backward projection of the lowest tracheal cartilage, forming a ridge between the openings of the right and left primary bronchi.
carotid body A small structure containing neural tissue at the bifurcation of the carotid arteries; it monitors the oxygen content of the blood and helps regulate respiration.
carotid sinus massage See *carotid sinus pressure*.
carotid sinus pressure A technique used to increase vagal tone to convert paroxysmal supraventricular tachycardia to sinus rhythm; also known as *carotid sinus massage*.
carpal Pertaining to the carpus, or wrist.
carpal tunnel syndrome An entrapment neuropathy that occurs when the median nerve becomes pressed or squeezed at the wrist in the carpal tunnel.
carpometacarpal joint The joint of the thumb.
carrier A radio signal of specific frequency generated by a transmitter without audio information imposed on it.
carrier molecule A protein that combines with solutes on one side of a membrane, transporting the solute to the other side; it is used in mediated transport mechanisms.
cartilage Firm, smooth, nonvascular connective tissue.
cartilaginous joint See *joint*.
catabolic Pertaining to the destruction of complex substances by living cells to form simple compounds.
cataract A loss of transparency of the lens of the eye that results from changes in the delicate protein fibers within the lens.
catecholamine Any of a group of sympathomimetic amines, including dopamine, epinephrine, and norepinephrine.
cathartic Causing evacuation of the bowel.
catheter fragment embolism The shearing or detachment of an IV catheter, allowing the embolus to travel in the bloodstream.
cation An ion with a positive charge.
cauda equina syndrome A rare disorder of the lumbar spine that affects the bundle of nerve roots at the lower end of the spinal cord; a surgical emergency.
cavitation A temporary or permanent opening produced by a force that pushes body tissues laterally away from the track of a projectile.
cecum A cul-de-sac constituting the first part of the large intestine.
cell The functional basic unit of life.
cell body The part of the cell that contains the nucleus and surrounding cytoplasm, exclusive of any projections or processes; it is concerned more with metabolism of the cell than with a specific function.
cell-mediated immunity Immunity characterized by the formation of a population of lymphocytes that attack and destroy foreign material.
cellular phone An 800- to 900-MHz radio communications system used to gain access to dial-up telephone circuits and vice versa. The system usually is divided into small coverage areas called cells, which are interconnected via microwave or dedicated telephone circuits.
cellulitis An inflammation of the skin characterized most commonly by local heat, redness, pain, swelling, and occasionally fever, malaise, chills, and headache.
cementum The bonelike connective tissue that covers the roots of the teeth and helps to support them.
centigram A metric unit of mass equal to $\frac{1}{100}$ of a gram.
centimeter A metric unit of length equal to $\frac{1}{100}$ of a meter, or 0.3937 inches.
central cord syndrome A spinal cord injury commonly seen with hyperextension or flexion cervical injuries; characterized by greater motor impairment of the upper than lower extremities.
central nervous system The brain and spinal cord.
central nervous system ischemic response An increase in blood pressure caused by vasoconstriction that occurs when oxygen levels are too low, carbon dioxide levels are too high, or pH is too low in the medulla.
central pain syndrome Infection or disease of the trigeminal nerve (cranial nerve V).
central retinal artery occlusion The blockage of blood supply to the arteries to the retina.
central thermoreceptors Nerve endings located in or near the anterior hypothalamus that are sensitive to heat.
centrifugation The process of separating components of different densities contained in a liquid by spinning them at high speeds.
centriole Usually paired organelles lying in the centrosome.
centrosome A specialized zone of cytoplasm close to the nucleus that contains two centrioles.
cephalic presentation A classification of fetal position in which the head of the fetus is at the uterine cervix; also known as *vertex presentation*.
cephalopelvic disproportion An obstetrical condition in which a newborn's head is too large or a mother's birth canal too small to permit normal labor or birth.
cephalothorax The united head and thorax of a spider.
cerebellar cortex The outer portion of the cerebellum.

cerebellum The second largest part of the brain, which plays an essential role in producing normal movements.
cerebral Pertaining to the brain.
cerebral aneurysm A weak or thin spot on a blood vessel in the brain that balloons and fills with blood; cerebral embolism.
cerebral aqueduct The narrow conduit between the third and fourth ventricles in the midbrain that conveys cerebrospinal fluid.
cerebral blood flow A function of cerebral perfusion pressure and resistance of the cerebral vascular bed.
cerebral cortex A thin layer of gray matter, made up of neuron dendrites and cell bodies, that composes the surface of the cerebrum.
cerebral edema An accumulation of fluid in the brain tissue.
cerebral palsy A general term for nonprogressive disorders of movement and posture.
cerebral perfusion pressure A measure of the amount of blood flow to the brain calculated by subtracting the intracranial pressure from the mean systemic arterial blood pressure.
cerebral thrombosis A blood clot (thrombus) forms in an artery that supplies blood to the brain.
cerebrospinal fluid Fluid that fills the subarachnoid space in the brain and spinal cord and in the cerebral ventricles.
cerebrospinal fluid rhinorrhea Leakage of cerebrospinal fluid caused by fracture of the ethmoid cribriform plate.
cerebrovascular accident An abnormal condition of the blood vessels of the brain characterized by occlusion by an embolus, thrombus, or cerebral hemorrhage; also known as *stroke and "brain attack."*
cerebrum The largest and uppermost part of the brain; it controls consciousness, memory, sensations, emotions, and voluntary movements.
certification (or registration) The process by which an agency or association grants recognition to an individual for meeting specific requirements to participate in an activity.
cerumen A yellowish or brownish waxy secretion produced in the external ear canal; also known as *earwax*.
ceruminous gland The gland that produces a waxy substance, cerumen (earwax).
cervical Pertaining to the neck.
cervical node One of the lymph glands in the neck.
cervical plexus The network of nerves formed by the ventral primary divisions of the first four cervical nerves.
cervical spondylosis A form of degenerative joint and disk disease that affects the cervical vertebrae and results in compression of the associated nerve roots.
cervical vertebrae The first seven segments of the vertebral column, designated C1 to C7.
cervicitis Acute or chronic inflammation of the uterine cervix.
cervix The lower part of the uterus.
cesarean delivery A surgical procedure in which the abdomen and uterus are incised and the baby is delivered transabdominally.
Chadwick's sign The bluish coloration of the vulva and vagina that develops after the sixth week of pregnancy as a normal result of local venous congestion; an early sign of pregnancy.
chalazion A small bump in the eyelid; caused by the blockage of a tiny oil gland in the upper or lower eyelid.
chancre A skin lesion, usually of primary syphilis, that begins at the site of infection as a papule and develops into a red, bloodless, painless ulcer with a craterlike appearance.
channel An assigned frequency or pair of frequencies used to carry voice or data communications or both. In emergency medical services, an advanced life support "MED" channel is a pair of radio frequencies, one used for transmitting, the other for receiving.
chemical name The exact designation of a chemical structure as determined by the rules of chemical nomenclature.
chemical restraint The use of drugs to control behavior.
chemoreceptor A sensory cell stimulated by a change in the concentration of chemicals to produce action potentials.
chemotactic factors Biochemical mediators that are important in activating the inflammatory response.
chemotaxis The response of leukocytes to products formed in immunological reactions; a part of the inflammatory response.
CHEMTREC (Chemical Transportation Emergency Center) A public service of the Chemical Manufacturers Association, the center provides immediate advice to on-scene personnel regarding management of hazardous materials.
Cheyne-Stokes respiration A regular, periodic pattern of breathing with equal intervals of apnea followed by a crescendo-decrescendo sequence of respirations.
chickenpox See *varicella*.
chief complaint A patient's primary complaint.
child abuse The physical, sexual, or emotional maltreatment of a child.
Chlamydia A genus of microorganisms that live as intracellular parasites; a common cause of sexually transmitted diseases and a frequent cause of sterility.
chlorine A poisonous, yellow-green gas with an odor that has been described as a mixture of pineapple and pepper.
choanal atresia A bony or membranous occlusion that blocks the passageway between the nose and pharynx; it can result in serious ventilation problems in the neonate.
cholecystectomy Surgical removal of the gallbladder.
cholecystitis Inflammation of the gallbladder, most often associated with the presence of gallstones.
cholecystokinin A hormone that stimulates the contraction of the gallbladder and the secretion of pancreatic juice.

cholesterol A fat-soluble compound found in animal fats and oils that is distributed widely in the body.
cholinergic Of or pertaining to the effects produced by the parasympathetic nervous system or drugs that stimulate or antagonize the parasympathetic nervous system.
chondrocytes Cartilage cells.
chorioamnionitis An inflammatory reaction in the amniotic membranes caused by organisms in the amniotic fluid.
chorionic gonadotropin A chemical component of the urine of pregnant women.
choroid The portion of the vascular tunic associated with the sclera of the eye.
choroid plexus A network of brain capillaries that are involved in producing cerebrospinal fluid.
chromatin granules The material within the cell nucleus from which chromosomes are formed.
chromosome An organized structure of DNA and protein that is found in cells.
chronic bronchitis Obstructive airway disease of the trachea and bronchi.
chronic fatigue syndrome A debilitating and complex disorder, characterized by profound fatigue that is not improved by bed rest and that may be worsened by physical or mental activity.
chronic gastroenteritis Inflammation of the stomach and intestines that accompanies numerous gastrointestinal disorders.
chronic obstructive pulmonary disease A progressive, irreversible condition characterized by diminished inspiratory and expiratory capacity of the lungs.
chronic pain Pain that continues or recurs over a prolonged period; it is caused by various diseases or by abnormal conditions.
chronic pulmonary hypertension A condition of abnormally high pressure within the pulmonary circulation.
chronic renal failure A progressive, irreversible systemic disease caused by kidney dysfunction that leads to abnormalities in blood counts and blood chemistry levels.
chronotropic Pertaining to agents that affect the heart rate; a drug that increases the heart rate is said to have a positive chronotropic effect.
chyme The semifluid mass of partly digested food passed from the stomach into the duodenum.
cilia Small, hairlike processes on the outer surfaces of some cells.
ciliary body A structure continuous with the choroid layer that contains smooth muscle cells and that functions in accommodation.
ciliated tissue Any tissue that projects cilia from its surface, such as portions of the epithelium in the respiratory tract.
circadian rhythm A pattern based on a 24-hour cycle, especially repetition of certain physiological phenomena, such as sleeping and eating.
circle of Willis The circle of interconnected blood vessels at the base of the brain.
circulatory shock Failure of the cardiovascular system to supply the cells with enough oxygenated blood to meet metabolic demands.
circumcision The surgical removal of the penile foreskin.
circumduction Movement in a circular motion.
circumflex artery The subdivision of the left coronary artery that feeds the lateral and posterior portions of the left ventricle and part of the right ventricle.
cirrhosis A chronic degenerative disease of the liver.
citrate Any salt or ester of citric acid.
classic heat stroke A severe, sometimes fatal condition resulting from the failure of the temperature-regulating capacity of the body; it is caused by prolonged exposure to the sun or to high temperatures.
claudication Cramplike pains in the calves caused by poor circulation of blood to the leg muscles.
clavicle A long, curved, horizontal bone just above the first rib that forms the ventral portion of the shoulder girdle.
clinical depression A disabling condition that adversely affects a person's family, work or school life, sleeping and eating habits, and general health; also known as *major depression.*
clinical perineum The portion of the perineum between the vaginal and anal openings.
clinical reasoning Use of the results of questions to think about associated problems and body system changes related to the patient's complaint.
clitoris Erectile tissue located in the vestibule of the vagina.
closed-ended questions Questions that are restrictive and can be answered with a "yes" or "no" response.
closed pneumothorax A collection of air or gas in the pleural space that causes the lung to collapse without exposing the pleural space to atmospheric pressure.
Clostridium difficile A bacterium that normally is present in small numbers in the intestines.
clotting cascade The blood-clotting system or coagulation pathway.
clotting factors Substances in the blood that act in sequence to stop bleeding by forming a clot.
cluster headache A type of headache that occurs in bursts (clusters); also known as *histamine headache.*
coagulation Formation of a clot.
coarse ventricular fibrillation Fibrillatory waves greater than 3 mm in amplitude.
coccygeal bone The four segments of the sacral vertebral column that fuse to form the adult coccyx.
coccygeal plexus A network of coccygeal nerves.
cochlea Part of the bony labyrinth of the inner ear.
cognitive development The construction of thought processes, including remembering, problem solving, and decision making, from childhood through adolescence to adulthood.
cognitive disorder A disorder that results in a disturbance of cognitive functioning.

coitus See *copulation*.

colitis An inflammatory condition of the large intestine characterized by severe diarrhea, bleeding, and ulceration of the mucosa of the intestine.

collagen The ropelike protein of the extracellular matrix.

collagen vascular disease Abnormal immune system activity with inflammation in the connective tissues; results in the accumulation of extra antibodies in the circulation.

collecting duct A straight tubule that extends from the cortex of the kidney to the tip of the renal pyramid.

Colles' fracture A fracture of the radius at the epiphysis within 1 inch of the joint of the wrist; it is easily recognized by the resultant dorsal and lateral position of the hand.

colloid A state of matter in which large molecules or aggregates of molecules that do not precipitate are dispersed in another medium.

colloid solutions Solutions that contain molecules (usually protein) that are too large to pass through the capillary membrane.

colon The portion of the large intestine that extends from the cecum to the rectum.

colorectal cancer A malignant disease of the large intestine characterized by a change in bowel habits and the passing of blood.

colostomy A surgical opening into the large intestine.

coma An abnormally deep state of unconsciousness where the patient cannot be aroused by external stimuli.

command The act of directing, ordering, or controlling by virtue of explicit, statutory, regulatory, or delegated authority.

command post The area from which command directs operations for an incident.

communicability period A stage of infection that begins when the latent period ends and continues as long as the agent is present and can spread to other hosts.

communicable disease An infectious disease that can be transmitted from one person to another.

communications The transmission and reception of information, resulting in common understanding.

communications center A facility used to dispatch emergency equipment and coordinate communications between field units and personnel.

community health assessment An assessment of a target community to identify needs and resources required to provide prevention and wellness promotion activities.

compact bone Hard, dense bone that usually is found at the surface of skeletal structures, as distinguished from cancellous bone.

compartment syndrome The result of a crush injury, usually caused by compressive forces or blunt trauma to muscle groups confined in tight fibrous sheaths with minimal ability to stretch.

compensated shock A stage of shock associated with some decreased blood flow and perfusion to the tissues.

competitive antagonist An agent with an affinity for the same receptor site as an agonist. The competition with the agonist for the site inhibits the action of the agonist; increasing the concentration of the agonist tends to overcome the inhibition.

complement One of 11 complex, enzymatic serum proteins; complement causes lysis in an antigen-antibody reaction.

complement system A group of proteins that coat bacteria; the proteins either help kill the bacteria directly or assist neutrophils (in the blood) and macrophages (in the tissues) to engulf and destroy the bacteria.

complete abortion An abortion in which the patient has passed all the products of conception.

complete breech A delivery presentation that occurs when the fetus has both knees and hips flexed; the buttocks are the presenting part.

complex partial seizure A seizure that originates in the temporal lobe; usually begins with an aura and is followed by repetitive motor behavior.

compliance The ease with which the lungs and thorax expand during pressure changes. The greater the compliance, the easier the expansion.

components of skeletal survey An x-ray study comprising a two-view chest with bone technique, two-view skull technique, views of the lateral lumbar spine and anteroposterior pelvis, and anteroposterior views of the upper and lower extremities, including anteroposterior views of the feet and posteroanterior views of the hands.

computer-aided dispatching An enhanced dispatch system in which computerized data are used to assist the dispatcher in selecting and routing emergency equipment and resources.

concealment A means of keeping out of site; it provides no ballistic protection.

concentration gradient The concentration difference between two points in a solution divided by the distance between the points.

concept formation A component of critical thinking that refers to all elements that are gathered to form a general impression of the patient.

concha The three bony ridges on the lateral wall of the nasal cavity.

concussion A head injury that results from violent jarring or shaking, such as that caused by a blow or explosion.

condyle A rounded projection on a bone, usually for articulation with another bone.

cone A photoreceptor in the retina of the eye; it is responsible for color vision.

confabulation The invention of stories to make up for gaps in memory.

congenital Present at birth.

congenital anomalies Defects that occur during fetal development.

congenital rubella syndrome A serious disease that affects about 25% of infants born to women infected with rubella during the first trimester of pregnancy; it is

associated with multiple congenital anomalies, mental retardation, and an increased risk of death from congenital heart disease and sepsis during the first 6 months of life.

congestive heart failure An abnormal condition that reflects impaired cardiac pumping, usually a result of myocardial infarction, ischemic heart disease, or cardiomyopathy.

conjugate gaze Deviation of both eyes to either side at rest; the condition implies a structural lesion.

conjunctiva A mucous membrane that covers the anterior surface of the eyeball and the lining of the eyelids.

conjunctivitis Inflammation of the conjunctiva, caused by bacterial or viral infection, allergy, or environmental factors.

connective tissue Tissue that supports and binds other body tissues and parts.

conservation of energy law The principle that energy can be neither created nor destroyed; it can only change from one form (mechanical, thermal, electrical, or chemical) to another.

constipation Difficulty passing stools, or incomplete or infrequent passage of hard stools.

contact dermatitis Skin rash that results from exposure to an irritant or sensitizing antigen.

continence The ability to control bladder or bowel function.

continuous positive airway pressure Airway support that transmits positive pressure into the airways of a spontaneously breathing patient throughout the respiratory cycle.

continuous quality improvement A management approach to customer service and organizational performance that includes constant monitoring, evaluation, decisions, and actions.

contracture deformity An abnormal, usually permanent condition of a joint characterized by flexion and fixation and caused by atrophy and shortening of muscle fibers or by loss of elasticity of the skin.

contraindications Medical or physiological factors that make it harmful to administer a medication that would otherwise have a therapeutic effect.

contralateral Affecting or originating in the opposite side of the body.

contrastimulant A factor that works against stimulation.

contrecoup An injury that occurs at a site opposite the side of impact.

control console Typically, a desk-mounted, enclosed piece of equipment that contains the mechanical and electronic controls used to operate a radio base station.

controlled substance Any drug defined in the categories of the Comprehensive Drug Abuse Prevention and Control Act (also known as the Controlled Substances Act) of 1970.

contusion A closed, soft tissue injury characterized by swelling, discoloration, and pain.

conversion disorder A mental illness in which painful emotions are repressed and unconsciously converted into physical symptoms.

copulation The sexual union of two persons of the opposite sex in which the penis is introduced into the vagina; also known as *coitus*.

cor pulmonale An abnormal cardiac condition characterized by hypertrophy of the right ventricle of the heart as a result of hypertension of the pulmonary circulation.

cord presentation A presentation that occurs when the cord slips down into the vagina or appears externally after the amniotic membranes have ruptured.

core body temperature The temperature of deep structures of the body as compared with temperatures of peripheral tissues.

cornea The convex, transparent, anterior part of the eye.

corneal abrasion The rubbing off of the outer layers of the cornea.

corniculate cartilage A conical nodule of elastic cartilage that surrounds the apex of each arytenoid cartilage.

coronal plane See *frontal plane*.

coronary artery One of two arteries that arise from the base of the aorta and carry blood to the muscle of the heart.

coronary artery disease One of several abnormal conditions that affect the arteries of the heart and reduce the flow of oxygen and nutrients to the myocardium.

coronary sinus A short trunk that receives most of the veins of the heart and empties into the right atrium.

corpus callosum An arched mass of white matter in the depths of the longitudinal fissure; it is made up of the transverse fibers that connect the cerebral hemispheres.

corpus luteum A yellow endocrine body formed in the ovary at the site of a ruptured vesicular follicle immediately after ovulation.

corpus luteum cyst A type of cyst prone to rupture that forms as a result of hemorrhage in a mature corpus luteum.

cortisol A steroid hormone that occurs naturally in the body.

costal cartilages Cartilages that connect the sternum and the ends of the ribs; allow the chest to move in respiration.

costal margin The margin of the lower limit of the ribs.

costochondral Pertaining to the junction of the ribs and cartilage.

countershock A high-intensity, short-duration electrical shock applied to the area of the heart, resulting in total cardiac depolarization.

coup Local damage that occurs at the site of impact.

couplet Two premature ventricular contractions in a row.

cover A type of concealment that hides the body and offers ballistic protection.

coverage The area covered by radio communication. The generally accepted national emergency system standard is the "90/90" standard. This means that 90% of the

coverage area will have communication 90% of the time. Coverage usually is expressed as dead (no coverage), marginal (spotty), good (few problems), or excellent (no problems).

Cowper's glands See *bulbourethral glands.*

coxae The hip joints; the head of the femur and the acetabulum of the innominate bone.

crackle A fine, bubbling sound heard on auscultation of the lung; it is produced by air entering distal airways and alveoli that contain serous secretions.

cranial nerve One of 12 pairs of nerves that originate from a nucleus within the brain.

cranial vault The eight skull bones that surround and protect the brain; the brain case.

craniectomy Surgical removal of bone fragments from the cranium.

creatinine A chemical waste molecule that is generated from muscle metabolism.

cremaster muscle A thin muscle layer spreading out over the spermatic cord in a series of loops; it functions to draw the testis up toward the superficial inguinal ring in response to cold or stimulation of the nerve.

crenate The shrinking of red blood cells caused by exposure to a hypertonic solution.

crepitus A grating sound associated with rubbing of bone fragments.

Creutzfeldt-Jakob disease A rare and fatal brain disorder characterized by rapidly progressive dementia.

cricoid cartilage The most inferior laryngeal cartilage.

cricothyroid membrane The membrane joining the thyroid and cricoid cartilages.

cricothyrotomy An emergency incision into the larynx.

crime scene A location where any part of a criminal act has occurred, or a location where evidence relating to a crime may be found.

Crohn's disease A chronic, inflammatory bowel disease of unknown origin, usually affecting the ileum, the colon, or both structures.

croup An acute viral infection of the upper and lower respiratory tract that occurs primarily in infants and young children 3 months to 3 years of age; it is characterized by hoarseness, fever, a harsh and brassy cough, inspiratory stridor, and varying degrees of respiratory distress; also known as *laryngotracheobronchitis.*

crown The portion of the human tooth covered by enamel.

crowning The phase at the end of labor in which the fetal head is seen at the opening of the vagina.

crush injury Injury from exposure of tissue to a compressive force sufficient to interfere with the normal structure and metabolic function of the involved cells and tissues.

crush syndrome A life-threatening and sometimes preventable complication of prolonged immobilization; a pathological process that causes destruction, alteration, or both of muscle tissue.

crystalloid A substance in a solution that can be diffused through a semipermeable membrane.

crystalloid solutions Solutions created by dissolving crystals such as salts and sugars in water.

crystalluria The presence of crystals in the urine.

cubic centimeter A metric unit of length equal to $\frac{1}{100}$ of a meter.

Cullen's sign The appearance of irregularly formed hemorrhagic patches on the skin around the umbilicus.

cultural imposition Forcing one's beliefs, values, and patterns of behavior on people from another culture.

cumulative action The effect that occurs when several doses of a drug are administered or when absorption occurs more quickly than removal by excretion or metabolism or both.

cuneiform cartilage A small rod of elastic cartilage above the corniculate cartilages in the larynx.

CUPS system A method of patient status coding that assigns patients to one of four categories: Cardiopulmonary resuscitation, *U*nstable, *P*otentially unstable, and *S*table.

current health status A focus on the patient's current state of health, environmental conditions, and personal habits.

Cushing's disease A metabolic disorder resulting from the chronic and excessive production of cortisol by the adrenal cortex or by the administration of glucocorticoids in large doses for several weeks or longer; also known as *Cushing's syndrome.*

Cushing's reflex An attempt by the body to compensate for a decline in cerebral perfusion pressure by a rise in mean arterial pressure.

Cushing's syndrome A condition caused by an abnormally high circulating level of corticosteroid hormones, produced naturally by the adrenal glands.

cutaneous Of or pertaining to the skin.

cuticle The skinfold covering the root of the nail.

cyanotic Having bluish discoloration.

cystic medial necrosis Degenerative changes in the connective tissue of the aortic media.

cystitis Inflammation of the urinary bladder and ureters.

cytochrome oxidase A respiratory enzyme that functions in the transfer of electrons from cytochromes to oxygen, thus activating oxygen, which unites with hydrogen to form water.

cytochromes Proteins in the liver that play a role in drug detoxification.

cytology The study of cells.

cytomegalovirus A member of a group of large, species-specific, herpes-type viruses with a wide variety of disease effects.

cytoplasm All of the substance of a cell other than the nucleus.

cytoplasmic membrane The plasma membrane.

cytotoxic Pertaining to a pharmacological compound or other agent that destroys or damages tissue cells.

dartos muscle A layer of smooth muscle in the skin of the scrotum; it raises and lowers the testes in the scrotum in response to changes in ambient temperature.

data interpretation A component of critical thinking in which the examiner gathers the necessary data to form a field impression and working diagnosis.

date rape Nonconsensual sex between people who are already acquainted (e.g., friends, acquaintances, people who are dating).

DCAP-BTLS An acronym for wound assessment: *D*eformity *C*ontusions, *A*brasions, *P*enetrations or punctures, *B*urns, *T*enderness, *L*acerations, and *S*welling.

deafness A complete or partial inability to hear.

debriefing An activity in which rescuers and others involved in an emergency event discuss their feelings to relieve emotions and anxiety; it usually takes place 24 to 72 hours after the event.

decerebrate posturing A position in which a comatose patient's arms are extended and internally rotated and the legs are extended with the feet in forced plantar flexion; usually observed in patients who have compression of the brainstem.

deciduous tooth Any of the 20 teeth that appear normally during infancy.

deciliter A metric unit of volume equal to $\frac{1}{10}$ of a liter.

decoding The act of interpreting symbols and format.

decompression sickness A multisystem disorder that results when nitrogen in compressed air converts back from solution to gas, forming bubbles in the tissues and blood.

decontamination The process of making patients, rescuers, equipment, and supplies safe by eliminating harmful substances.

decorticate posturing A position in which the comatose patient's upper extremities are rigidly flexed at the elbows and at the wrists; usually observed in patients who have a lesion in the mesencephalic region of the brain.

dedicated line A special telephone circuit designated for specific point-to-point communication purposes, such as alerting emergency medical services quarters.

deep frostbite A cold injury that results in significant tissue loss even with appropriate therapy; it is associated with subdermal layers and deep tissues.

deep tendon reflexes Reflexes elicited by sensory afferents from muscle rather than bone.

deep vein thrombosis A disorder involving a thrombus in one of the deep veins of the body, most commonly the iliac and femoral veins.

defecation The elimination of feces from the digestive tract through the rectum.

defense mechanism An unconscious, intrapsychic reaction to protect the self from a stressful situation.

defibrillation The delivery of direct electrical current in an attempt to terminate ventricular fibrillation or pulseless ventricular tachycardia.

defibrillator A device used to depolarize fibrillating myocardial cells, thus allowing them to repolarize uniformly.

deficient ambient oxygen An oxygen concentration that is less than 21%.

defusing An informal gathering of the persons involved in an emergency event to allow an initial release of feelings and an opportunity for persons to share their experiences.

degloving injury An injury usually involving the hand or finger in which the soft tissue is removed down to the bone.

degradation The physical destruction or decomposition of clothing material caused by use, ambient conditions, or exposure to chemicals.

degranulation A cellular process that releases antimicrobial substances from secretory vesicles (granules) found inside mast cells and basophils; plays a role in allergic reactions.

dehydration An excessive loss of water from the body tissues; it may follow prolonged fever, diarrhea, vomiting, acidosis, and other conditions.

delirium An abrupt disorientation for time and place, usually with illusions and hallucinations.

delirium tremens An acute and sometimes fatal psychotic reaction caused by cessation of excessive intake of alcohol over a long period of time; also known as *DTs*.

delta cell A constituent of the islets of Langerhans; it secretes somatostatin.

delta wave Widened, abnormal slurring or notching of the onset of the QRS complex; it indicates anomalous spread of the impulse and is a diagnostic finding for Wolff-Parkinson-White syndrome.

deltoid muscle A large, thick, triangular muscle that covers the shoulder joint.

delusions Persistent beliefs or perceptions held by a person despite evidence that refutes them (i.e., false beliefs).

dementia A slow, progressive loss of awareness of time and place. It usually involves an inability to learn new things or recall recent events.

dendrite The branching processes of a neuron that receive stimuli and conduct potentials toward the cell body.

dental abscess A bacterial infection in the center of the tooth.

dentalgia The medical term for toothache.

dentin The chief component of teeth, surrounding the pulp and situated inside the enamel and cementum.

deoxyribonucleic acid A type of nucleic acid that comprises the genetic material of cells.

dependent lividity A red or bluish purple tissue condition in dependent areas of the body caused by venous congestion.

depersonalization Forced emotional estrangement.

depolarization A change in electrical charge difference across the cell membrane that causes the difference to be smaller or closer to 0 mV; a phase of the action potential in which the membrane potential moves toward zero or becomes positive.

depressant A substance that decreases or lessens a body function or activity.

depressed skull fracture Any fracture of the skull in which fragments are depressed below the normal surface of the skull.

depression A mood disturbance characterized by feelings of sadness, despair, and discouragement.

dermatitis Inflammation of the skin.

dermatome The skin surface area supplied by a single spinal nerve.

dermatomyositis An inflammatory myopathy characterized by a skin rash that precedes or accompanies progressive muscle weakness.

dermis Dense, irregular connective tissue that forms the deep layer of the skin.

descending colon The segment of the colon that extends from the end of the transverse colon at the splenic flexure on the left side of the abdomen down to the beginning of the sigmoid colon in the pelvis.

desensitization Emotional insensitivity.

designated officer A person who serves as a liaison between the public safety agency and community health agencies involved in monitoring and responding to communicable diseases.

diabetes insipidus A metabolic disorder characterized by extreme polyuria and polydipsia, caused by deficient production or secretion of antidiuretic hormone or inability of the kidney tubules to respond to antidiuretic hormone.

diabetes mellitus A complex disorder of carbohydrate, fat, and protein metabolism that primarily results from partial or complete lack of insulin secretion by the beta cells of the pancreas or of defects of the insulin receptors.

diabetic ketoacidosis An acute, life-threatening complication of uncontrolled diabetes characterized by hyperglycemia, hypovolemia, electrolyte imbalance, and a breakdown of free fatty acids, causing acidosis; also known as *diabetic coma*.

diad The combination of sarcoplasmic reticulum and T tubules.

diagnosis Identification of a disease or condition by an evaluation of physical signs, symptoms, history, laboratory tests, and procedures.

dialysate A solution used in dialysis.

dialysis A technique used to normalize blood chemistry in patients with acute or chronic renal failure and to remove blood toxins in some patients who have taken a drug overdose.

dialysis fistula An artificial passage, as in an arteriovenous fistula, used to gain access to the patient's bloodstream for hemodialysis.

diaphoresis Profuse secretion of sweat.

diaphragm The dome-shaped, musculofibrous partition that separates the thoracic and abdominal cavities.

diaphragmatic hernia A herniation in the diaphragm caused by the improper fusion of structures during fetal development.

diaphysis The shaft of a long bone, consisting of a tube of compact bone that encloses the medullary cavity.

diarrhea The frequent passage of loose, watery stools; it is generally the result of increased motility in the colon.

diastolic blood pressure The minimum level of blood pressure measured between contractions of the heart.

diencephalon The parts of the brain between the cerebral hemispheres and the mesencephalon.

differential count A laboratory test that identifies the different types of leukocytes present in blood; also called the *diff*.

differential diagnosis The process of weighing the probability of one disease versus that of other diseases possibly accounting for a patient's illness.

differentiation A process in which cells become specialized in one type of function or act in concert with other cells to perform a more complex task.

diffusion The process in which solid, particulate matter in a fluid moves from an area of higher concentration to an area of lower concentration, resulting in an even distribution of the particles in the fluid.

dilation and curettage A gynecological procedure that refers to widening of the uterine cervix and scraping away of the endometrium of the uterus.

diphtheria An acute contagious disease characterized by the production of a systemic toxin and a false membrane lining of the mucous membranes of the throat.

diplopia Double vision.

direct laryngoscopy Visual examination of the larynx with a laryngoscope.

disease period A stage of infection that follows the incubation period; the duration of this period varies with the disease.

disentanglement The process of making a pathway through the wreckage of an accident and removing wreckage from patients.

disequilibrium Unstable equilibrium; motion sickness.

disequilibrium syndrome A group of neurological findings that sometimes occur during or immediately after dialysis; thought to result from a disproportionate decrease in osmolality of the extracellular fluid compared with that of the intracellular compartment in the brain or cerebrospinal fluid.

diskectomy The surgical removal of a vertebral disk.

disoriented Unaware of surroundings.

dispositional hearing The phase of the family court process in which appropriate placement for a child and appropriate treatment, if any, for the parent of a child are determined and ordered.

dissecting aortic aneurysm Localized dilation of the aorta characterized by a longitudinal dissection between the outer and middle layers of the vascular wall.

disseminated intravascular coagulation A grave coagulopathy that results from the overstimulation of the clotting and anticlotting processes in response to disease or injury.

dissociative disorders A group of psychological illnesses. In these illnesses, a particular mental function is separated (dissociated) from the mind as a whole.

dissolution The rate at which a solid drug goes into solution after ingestion; the faster the rate of dissolution, the more quickly the drug is absorbed.

distraction (1) A self-defense measure in which a diversion is created to draw a person's attention. (2) A spinal injury that occurs if the cervical spine is suddenly stopped while the weight and momentum of the body are pull away from it.

distress Negative, debilitating, or harmful stress.

distribution The transport of a drug through the bloodstream to various tissues of the body and ultimately to its site of action.

distributive shock Shock that occurs when peripheral vasodilation causes a fall in systemic vascular resistance.

disulfiram-ethanol reaction A potentially life-threatening physiological response caused by disulfiram and ethanol that produces ill effects on the gastrointestinal, cardiovascular, and autonomic nervous systems; disulfiram is prescribed to some alcoholic patients to help them maintain abstinence.

diuresis The increased formation and secretion of urine.

diversity Differences of any kind: race, class, religion, gender, sexual preference, personal habitat, and physical ability.

diverticulitis Inflammation of one or more diverticula.

diverticulosis The presence of pouchlike herniations through the muscular layer of the colon.

diverticulum A pouchlike herniation through the muscular wall of a tubular organ; it may be present in the stomach, small intestine, or, most commonly, the colon.

divisions Subdivisions of the incident command system that encompass specific geographical areas of responsibility as deemed necessary by the incident commander.

do not resuscitate A physician order instructing emergency care providers not to attempt resuscitation of a patient in the event of cardiac or respiratory failure; also known as a *"no code" order*.

dorsal root A sensory component that conveys afferent nerve processes to the spinal cord.

dorsal root ganglia See *spinal ganglia*.

dorsogluteal site An area made up of several gluteal muscles; it is used as an injection site.

Down syndrome A congenital condition characterized by varying degrees of mental retardation and multiple defects.

dram A unit of mass equal to an apothecary measure of 60 gr or ⅛ oz.

dromotropic Pertaining to agents that affect conduction velocity through the conducting tissues of the heart; a drug that speeds conduction is said to have a positive dromotropic effect.

drowning A mortal event in which a submersion victim is pronounced dead at the scene of the attempted resuscitation, or within 24 hours after arrival in the emergency department or hospital.

drug Any substance taken by mouth; injected into a muscle, blood vessel, or cavity of the body; or applied topically to treat or prevent a disease or condition.

drug absorption A process in which drug molecules move from the site of entry into the body to the general circulation.

drug abuse Self-medication or self-administration of a drug in chronically excessive amounts, resulting in psychological or physical dependence (or both), functional impairment, and deviation from approved social norms.

drug allergy A systemic reaction to a drug resulting from previous sensitizing exposure and the development of an immunological mechanism.

drug dependence A state in which intense physical or emotional disturbance is produced if a drug is withdrawn; previously called *habituation*.

drug interaction Modification of the effects of one drug by the previous or concurrent administration of another drug, thereby increasing or diminishing the pharmacological or physiological action of one or both drugs.

drug receptors Parts of a cell (usually an enzyme or large protein molecule) with which a drug molecule interacts to trigger its desired response or effect.

drug-protein complex A complex formed by the attachment of a drug to proteins, mainly albumin.

ductus arteriosus A vascular channel in the fetus that joins the pulmonary artery directly to the descending aorta.

ductus deferens A thick, smooth muscular tube that allows sperm to exit from the epididymis through the ejaculatory duct; also known as the *vas deferens*.

ductus venosus The continuation of the umbilical vein through the liver to the inferior vena cava.

duodenum The first subdivision of the small intestine.

duplex mode A communications mode with the ability to transmit and receive traffic simultaneously through two different frequencies, one to transmit and one to receive.

duplex/multiplex system A communications system with the ability to transmit and receive simultaneously with concurrent transmission of voice and telemetry.

dura mater The outermost layer of the meninges.

duration of action The period from the onset of drug action to the time when a drug effect is no longer seen.

dysarthria Difficult and poorly articulated speech resulting from poor control over the muscles of speech.

dysconjugate gaze Deviation of the eyes to opposite sides at rest; it implies a structural brainstem dysfunction in the pathways that traverse the brainstem from the upper midbrain to at least the level of the lower pons.

dysfunctional uterine bleeding Abnormal bleeding that occurs because of changes in hormone levels.

dyshemoglobinemia Hemoglobin saturated with compounds other than oxygen, such as carbon monoxide or methemoglobin.

dyskinesia An impairment of the ability to execute voluntary movements; often an adverse effect of prolonged use of antipsychotic medications.

dysmenorrhea Pain associated with menstruation.
dyspareunia Pain with intercourse.
dysphagia Inability or difficulty in swallowing because of medical or traumatic causes.
dysphonia An abnormality in the speaking voice, such as hoarseness.
dysplasia Abnormal cellular growth.
dyspnea Difficulty breathing.
dysrhythmia Variation from a normal rhythm.
dysthymia A form of depression that is chronic in nature, lasting as long as 2 years or more.
dystonia A condition characterized by local or diffuse changes in muscle tone, resulting in painful muscle spasms, unusually fixed postures, and strange movement patterns.
dysuria Difficult urination.
EACOM/HEAR The Emergency Administrative Communications (by General Electric) or Hospital Emergency Administrative Radio (by Motorola). These radio systems use 1500-Hz rotary-pulse dialing, which transmits specific groups of rotary tone pulses for the purpose of selectively addressing hospital-based receivers in particular regions throughout the United States. Most ambulance services have access to this system.
eardrum The cellular membrane that separates the external ear from the middle ear; also known as the *tympanic membrane.*
early adulthood Persons 20 to 40 years of age.
eating disorders A term referring to anorexia nervosa and bulimia nervosa, conditions in which dissatisfaction with weight and body shape cause an individual to develop disordered eating behaviors.
eclampsia A grave form of pregnancy-induced hypertension, characterized by convulsions, coma, proteinuria, and edema.
ectoparasite An organism that lives on the outside of the body of the host, such as a louse.
ectopic Out of place.
ectopic foci Cardiac dysrhythmias caused by irritation of an excitation impulse at a site other than the sinus node.
ectopic pregnancy An abnormal pregnancy in which the conceptus implants outside the uterine cavity.
eczema Superficial dermatitis of unknown cause.
edema The accumulation of fluid within the interstitial spaces.
effacement The shortening of the vaginal portion of the cervix and the thinning of its walls as it is stretched and dilated by the fetus during labor.
effective dose 50 The amount of drug that produces a therapeutic response in 50% of those who take it.
effector organ A muscle or gland that responds to nerve impulses from the central nervous system.
efferent division The division of the central nervous system that transmits action potentials to effector organs such as muscles and glands.
efferent neuron Nerve fibers that send impulses from the central nervous system to the periphery.
efficacy An intrinsic activity that refers to the ability of a drug to initiate biological activity as a result of such binding.
Einthoven's triangle An equilateral triangle formed by the patient's right arm, left arm, and left leg; it is used in electrode sensor placement for electrocardiogram monitoring.
ejaculatory duct A duct formed by the joining of the ductus deferens and the duct from the seminal vesicle that allows sperm to enter the urethra.
ejection The forceful expulsion of blood from the ventricle of the heart.
elastin The major connective tissue protein of elastic tissue; it has a structure like a coiled spring.
elder abuse The infliction of physical pain, injury, debilitating mental anguish, unreasonable confinement, or willful deprivation by a caregiver of services that are necessary to maintain mental and physical health of a geriatric person.
electroconvulsive therapy Induction of a brief convulsion by passing an electrical current through the brain to treat affective disorders.
electrolyte A cation or anion in solution that conducts an electrical current.
elevation Movement of a structure in a superior direction.
ellipsoid joint A modified ball-and-socket joint in which the articular surfaces are ellipsoid rather than spherical.
emaciated To be abnormally lean from disease or lack of nutrition.
embolectomy A surgical incision into an artery for the removal of an embolus or clot.
embolus A blockage or free-moving thrombus in a blood vessel.
embryo In human beings the stage of prenatal development between the time of implantation of the fertilized ovum until the end of the seventh or eighth week.
emergency medical services A national network of services coordinated to provide aid and medical assistance from primary response to definitive care; the network involves personnel trained in rescue, stabilization, transportation, and advanced management of traumatic and medical emergencies.
emissary veins The small vessels in the skull that connect the sinuses of the dura with the veins on the exterior of the skull through a series of anastomoses.
emotional abuse The infliction of anguish, pain, or distress through verbal or nonverbal acts.
emotional/mental impairment Impaired intellectual functioning that results in an inability to cope with normal responsibilities of life.
empathy The ability to see a situation from the viewpoint of the person experiencing it.
emphysema An abnormal condition of the pulmonary system characterized by overinflation and destructive changes in the alveolar walls, resulting in a loss of lung elasticity and a decrease in gases.

EMS communications The delivery of patient and scene information (either in person, in writing, or through communications technology) to other members of the emergency response team.

enamel A hard white substance that covers the dentin of the crown of the tooth.

encephalitis An inflammatory condition of the brain, usually caused by an infection transmitted by the bite of an infected mosquito; it also may result from lead or other poisoning or from hemorrhage.

encoding The act of placing a message in an understandable format (either written or verbal).

end-stage renal disease Complete, or near-complete, failure of the kidneys to function.

endocrine gland A gland that secretes chemicals and hormones directly into the blood, rather than through a duct.

endolymph Fluid found within the membranous labyrinth.

endometriosis An abnormal gynecological condition characterized by ectopic growth and function of endometrial tissue; it is thought to result when, during menstruation, fragments of endometrium from the lining of the uterus are regurgitated backward through the fallopian tubes into the peritoneal cavity, where they attach and grow as small cystic structures.

endometritis An inflammatory condition of the endometrium, usually caused by bacterial infection.

endometrium The mucous membrane lining of the uterus, which changes in thickness and structure with the menstrual cycle.

endoplasmic reticulum A network of connecting sacs or canals that wind through the cytoplasm of a cell and serve as a miniature circulatory system for the cell.

endorphin Any of several peptides secreted in the brain that have a pain-relieving effect like morphine.

endotoxin A toxin contained in the cell walls of some microorganisms, especially gram-negative bacteria.

endotracheal intubation An airway management procedure in which an endotracheal tube is inserted through the mouth or nose into the trachea. Intubation is used to maintain a patent airway, to prevent aspiration of material from the digestive tract, to permit suctioning of tracheobronchial secretions, to administer positive-pressure ventilation, and to administer certain medications when other means of vascular access are unavailable.

endotracheal route Refers to drugs administered through an endotracheal tube.

enhanced automaticity The cause of dysrhythmias in Purkinje fibers and other myocardial cells with a high resting membrane potential; it results from an acceleration of phase 4 depolarization commonly caused by abnormally high leakage of sodium ions into the cells, which causes the cells to reach threshold prematurely.

enophthalmos An abnormal condition characterized by recession of the eyeball within the orbit.

enteral route A route of drug administration along any portion of the gastrointestinal tract.

envenomation The injection of snake, arachnid, or insect venom into the body.

enzyme A protein produced by living cells that catalyzes chemical reactions in organic matter.

eosinophil A white blood cell that inhibits inflammation; thought to deactivate leukotrienes.

eosinophil chemotactic factor of anaphylaxis A group of active substances, including histamine and leukotrienes, that are released during an anaphylactic reaction.

epicardium See *visceral pericardium*.

epicondyle A projection on the surface of a bone above its condyle.

epidermis The outer portion of skin; it is formed of epithelial tissue that rests on or covers the dermis.

epididymis A tightly coiled tube that lies along the top of and behind the testes, where sperm mature.

epididymitis An inflammation of the epididymis, a tubular section of the male reproductive system that carries sperm from the testicles to the seminal vesicles.

epidural hematoma Accumulation of blood between the dura mater and the cranium.

epidural space The space above or on the dura.

epiglottis A lidlike cartilage that overhangs the entrance to the larynx.

epiglottitis Inflammation of the epiglottis; a severe form of the condition that affects primarily children is characterized by fever, sore throat, stridor, croupy cough, and an erythematous epiglottis.

epilepsy A condition characterized by a tendency of the individual to have recurrent seizures (excluding those that arise from correctable or avoidable circumstances).

epinephrine Adrenaline, a hormone secreted by the adrenal medulla.

epiphyseal line A dense plate in a bone that is no longer growing, indicating the former site of the epiphyseal plate.

epiphyseal plate See *growth plate*.

epiphysis The head of a long bone that is separated from the shaft of the bone by the epiphyseal plate until the bone stops growing, the plate is obliterated, and the shaft and the head are united.

epistaxis Bleeding from the nose.

epithelial tissue The cellular covering of internal and external surfaces of the body, including the lining of vessels and other small cavities.

Epstein-Barr virus The herpesvirus that causes infectious mononucleosis.

erection The condition of hardness, swelling, and elevation observed in the penis and to a lesser degree in the clitoris, usually caused by sexual arousal.

erythema Redness of the skin, caused by hyperemia of the capillaries in the lower layers of the skin.

erythrocyte A red blood cell.

escape beat An automatic beat of the heart that occurs after an interval longer than the duration of the dominant heartbeat cycle.

eschar A scab or dry crust resulting from a thermal or chemical burn.

escharotomy Surgical incision into necrotic tissue caused by a severe burn; escharotomy sometimes is necessary to prevent edema from causing sufficient interstitial pressure to impair capillary filling and lead to ischemia.

esophageal reflux A chronic disease manifested by various sequelae associated with reflux of the stomach and duodenal contents into the esophagus.

esophageal stricture An abnormal temporary or permanent narrowing of the esophagus caused by inflammation, external pressure, or scarring.

esophagitis Inflammation of the esophagus.

esophagogastric varices A complex of longitudinal, tortuous veins at the lower end of the esophagus that become large and swollen as a result of portal hypertension; also known as *esophageal varices*.

esophagus The muscular canal extending from the pharynx to the stomach.

estimated date of confinement Delivery date for the fetus.

estrogen One of a group of hormonal steroid compounds that promote the development of female secondary sex characteristics.

ethics The discipline relating to right and wrong, moral duty and obligation, moral principles and values, and moral character; a standard for honorable behavior designed by a group with expected conformity.

ethmoid bone The very light, spongy bone at the base of the cranium that forms most of the walls of the superior part of the nasal cavity.

ethmoid sinus One of the numerous small, thin-walled cavities in the ethmoid bone of the skull, rimmed by the frontal maxilla and the lacrimal, sphenoidal, and palatine bones.

ethnocentrism Seeing one's own life as the most acceptable or best; acting in a superior manner toward another culture's way of life.

ethylene glycol A chemical used in automobile antifreeze preparations.

eukaryote A cell with a true nucleus, found in all higher organisms and in some microorganisms.

eustachian tube See *auditory tube*.

eustress Positive, performance-enhancing stress.

evaluation A component of critical thinking in which the examiner assesses the patient's response to care.

evasive tactics A self-defense measure in which an aggressor's moves and actions are anticipated, and unconventional pathways are used during retreat for personal safety.

eversion Turning outward.

evisceration The protrusion of an internal organ through a wound or surgical incision, especially in the abdominal wall.

excitability The property of a cell that enables it to react to irritation or stimulation.

excretion The elimination of toxic or inactive metabolites, primarily by the kidneys; the intestines, lungs, and mammary, sweat, and salivary glands also may be involved.

excursion Movement from side to side.

exertional heat stroke An abnormal condition characterized by weakness, vertigo, nausea, muscle cramps, and loss of consciousness; caused by depletion of body fluid and electrolytes resulting from exposure to intense heat or inability to acclimatize to heat.

exocrine gland A gland that secretes chemicals and hormones into a duct.

exophthalmos An abnormal condition characterized by marked protrusion of the eyeballs.

exothermic Marked or accompanied by the evolution of heat.

exotoxin A toxin secreted or excreted by a living organism.

expiration Breathing out (exhalation), normally a passive process.

expiratory center The region of the medulla that is electrically active during nonquiet expiration.

expiratory reserve volume The maximum volume of air that can be exhaled after expiration of the normal tidal volume.

exposure incident Any specific contact of the eyes, the mouth, other mucous membranes, nonintact skin, or parenteral contact with blood, blood products, bloody body fluids, or other potentially infectious materials.

expressed consent Verbal or written consent to the treatment.

extended scope of practice The expansion of health care services provided by emergency medical technicians and paramedics in the prehospital setting.

extension Stretching out.

external anal sphincter A sphincter muscle located at the tip of the coccyx and surrounding fascia; it prevents the movement of feces out of the rectum until it is relaxed.

external auditory canal The passage for sound impulses passing through the ear.

external auditory meatus The canal of the external ear; also known as the *external auditory canal.*

external barriers The surface of the body that is exposed to the environment. This includes the skin and the mucous membranes of the digestive, respiratory, and genitourinary tracts; the body's first line of defense against infection.

external cardiac pacing The delivery of repetitive electrical currents to the heart, substituting for a natural pacemaker that has become blocked or dysfunctional; also known as *transcutaneous cardiac pacing.*

external ear The portion of the ear that includes the auricle and external auditory meatus; it terminates at the eardrum.

external genital organs The outer parts of the female genitalia; consist of the labia majora, the labia minora, Bartholin's glands, and the clitoris. Also known as *vulva.*

external jugular vein One of a pair of large vessels in the neck that receive most of the blood from the exterior of the cranium and deep tissues of the face.

external respiration The transfer (diffusion) of oxygen and carbon dioxide between the inspired air and pulmonary capillaries.

external urinary sphincter The smooth muscle that surrounds the urethra as the urethra extends through the pelvic floor; it controls the flow of urine through the urethra.

extracellular Occurring outside of a cell or cell tissues or in cavities or spaces between cell layers or groups of cells.

extracellular fluid The water found outside the cells, including that in the intravascular and interstitial compartments.

extracellular matrix Nonliving chemical substances located between connective tissue cells.

extrapyramidal reaction A response to a treatment or drug characterized by involuntary movement, changes in muscle tone, and abnormal posture.

extravasation The passage or escape of blood, serum, or lymph into the tissues.

extubation Removal of an endotracheal tube.

exudate Fluid, cells, or other substances that have been discharged slowly from cells or blood vessels through small pores or breaks in cell membranes.

face presentation An abnormal presentation in which the brow or forehead of the fetus is the first part of the body to enter the birth canal; also known as *brow presentation.*

facial bones The 14 bones that form the structure of the face in the anterior skull; they do not contribute to the cranial vault.

facial nerve palsy Partial or total loss of the functions of the facial muscles or loss of sensation in the face.

facies A facial expression or appearance.

facilitated diffusion A carrier-mediated process that moves substances into or out of cells from a high to a low concentration.

factitious disorders A group of disorders in which symptoms mimic a true illness. However, the symptoms have actually been invented.

failure to thrive The abnormal retardation of the growth and development of an infant resulting from conditions that interfere with normal metabolism, appetite, and activity.

fallopian tube See *uterine tube.*

false imprisonment Intentional and unjustifiable detention of a person.

false movement An unnatural movement of an extremity, usually associated with fracture.

false rib See *rib.*

false vocal cord See *vestibular fold.*

family court Sometimes referred to as juvenile court; the court is authorized to handle proceedings involving claims of abuse and neglect, dependency, delinquency, and requests for the termination of parental rights.

family function Refers to how a family deals with daily problems and conflicts, and whether this is done in a respectful, productive, and nonaggressive way.

family history Illness or disease in a patient's family or a family's background that may be relevant to the patient's complaint.

fascia The loose areolar connective tissue found beneath the skin or dense connective tissue that encloses and separates muscle.

fascicle A small bundle or cluster of nerve or muscle fibers that provides pathways for impulse conduction.

fasciculation A localized, uncoordinated, uncontrollable twitching of a single muscle group that can be palpated and seen under the skin.

fasciitis Inflammation of the fascia.

fasciotomy Incision of a fascia to relieve elevated intracompartmental pressure.

fat A substance composed of lipids or fatty acids.

Fc receptor A protein found on the surface of certain cells that contribute to the protective functions of the immune system. Fc receptors bind to antibodies that are attached to infected cells or invading pathogens.

febrile seizure A seizure that results from fever.

fecal impaction An accumulation of hardened feces in the rectum or sigmoid colon that the person is unable to move.

fecalith A hard, impacted mass of feces in the colon.

feces Waste material discharged from the intestines.

Federal Communications Commission A federal agency with jurisdiction over interstate and international telephone and telegraph services and satellite communications.

femoral vein A large vein in the thigh that originates in the popliteal vein and accompanies the femoral artery in the proximal two thirds of the thigh.

femur The thigh bone, which extends from the pelvis to the knee; the largest and strongest bone in the body.

fetal membrane disorder One of several disorders that pertain to the fetus or to the period during its development, including premature rupture of membranes, amniotic fluid embolism, and meconium staining.

fetus Unborn young, from the third month of the intrauterine period until birth.

fibrinogen A soluble blood protein converted into insoluble fibrin during clotting.

fibrocartilage Cartilage that consists of a dense matrix of white collagenous fibers.

fibromyalgia A disorder that causes extreme fatigue; associated with "tender points" on the neck, shoulders, back, hips, arms, and legs.

fibrosis An abnormal condition in which fibrous connective tissue spreads over or replaces normal smooth muscle or other normal organ tissue.

fibrous connective tissue A connective tissue that consists mainly of bundles of strong, white collagenous fibers arranged in parallel rows.

fibrous joint See *joint*.

fibrous pericardium Fibrous outer layer of the heart.

fibrous tunic The sclera and cornea.

fibula One of the two bones of the lower leg, lateral to and smaller than the tibia.

Fick principle The principle used to determine cardiac output. It assumes that the quantity of oxygen delivered to an organ is equal to the amount of oxygen consumed by that organ plus the amount of oxygen carried away from that organ.

field impression An impression of the patient's condition that the paramedic makes from pattern recognition and gut instinct that results from experience.

filtrate A filtered liquid.

filtration Movement caused by a pressure gradient of a liquid through a filter that prevents some or all of the substances in the liquid from passing through the filter.

fimbria A fringelike structure located at the border of the uterine tube.

financial/material exploitation The illegal or improper use of funds, properties, or assets.

fine ventricular fibrillation Fibrillatory waves less than 3 mm in amplitude.

first stage of labor The stage of labor that begins with the onset of regular contractions and ends with complete dilation of the cervix.

first-degree burn A burn injury in which only a superficial layer of epidermal cells is destroyed.

first-pass metabolism The initial biotransformation of a drug during passage through the liver from the portal vein that occurs before the drug reaches the general circulation.

fistula An abnormal passage from an internal organ to the body surface.

flail chest A chest wall injury in which three or more adjacent ribs are fractured in two or more places.

flat bones Bones that have a thin, flattened shape, such as certain skull bones, the ribs, the sternum, and scapulae.

flatulence Excessive air or gas in the stomach or intestinal tract, causing distention of the organs and in some cases mild to moderate pain.

flexion Bending.

flexor tenosynovitis A pathological state that causes a disruption of tendon function in the hand; usually the result of infection.

floating rib See *rib*.

flora Microorganisms that live on or in the body to compete with disease-producing microorganisms and provide a natural immunity against certain infections.

flutter waves Abnormal P waves in a sawtooth or picket fence pattern; they represent atrial depolarization in an abnormal direction followed by atrial repolarization.

focal seizure See *jacksonian seizure*.

focused history A component of patient assessment to ascertain the patient's chief complaint, history of present illness, medical history, and current health status.

fontanelle A space covered by a tough membrane between the bones of an infant's cranium.

food poisoning Poisoning that results from food contaminated by toxic substances or by bacteria containing toxins.

foramen ovale An opening in the septum between the right and left atria in the fetal heart; it provides a bypass for blood that would otherwise flow to the fetal lungs.

foreign body airway obstruction A disturbance in normal function or a pathological condition caused by an object lodged in the airway.

formed elements Cells and cell fragments of blood.

formic acid A colorless, pungent liquid found in nature in ants and other insects.

Fournier's gangrene A bacterial infection of the skin that affects the genitals and perineum in both men and women.

fourth ventricle The ventricle located in the superior region of the medulla; continuous with the central canal of the spinal cord.

fourth-degree burn A full-thickness burn injury that penetrates the subcutaneous tissue, muscle, fascia, periosteum, or bone.

fracture A break in the continuity of bone or cartilage.

frank breech See *front breech.*

fraternal twins Two offspring born of the same pregnancy from two ova released simultaneously from the ovary and fertilized at the same time.

French scale system A scale used to denote the size of catheters and other tubular instruments; each unit is roughly equivalent to 0.33 mm in diameter.

frequency The number of repetitive cycles per second completed by a radio wave.

frequency modulation A deviation of carrier frequency in accordance with the strength of applied audio. Frequency modulation is less susceptible to some types of interference than amplitude modulation and typically is used in emergency medical services communications.

front breech A presentation that occurs when the fetal hips are flexed and the legs extend in front of the fetus, making the buttocks the presenting part; also known as a *frank breech.*

frontal bone The single cranial bone that forms the front of the skull.

frontal lobe The largest of the five lobes that comprise each of the two cerebral hemispheres; it significantly influences personality and is associated with higher mental activities such as planning, judgment, and conceptualization.

frontal plane An imaginary plane that divides the body into front and back or anterior and posterior positions; also known as the *coronal plane.*

frontal sinus One of a pair of small cavities in the frontal bone of the skull that communicates with the nasal cavity.
frostbite A localized injury that results from environmentally induced freezing of body tissues.
frostnip The mildest form of cold injury; it may be treated without loss of tissue.
full-thickness burn A burn injury in which the entire thickness of the epidermis and dermis is destroyed; also known as a *third-degree burn*.
functional residual capacity The expiratory reserve volume plus the residual volume; it reflects the amount of gas remaining in the lungs at the end of a normal expiration.
fundus The bottom or rounded end of a hollow organ, such as the fundus of the uterus.
fusion beat A premature ventricular contraction that occurs at approximately the same time that an electrical impulse of the underlying rhythm is activating the ventricles, thereby causing ventricular depolarization to occur simultaneously in two directions; it results in a QRS complex that has the characteristics of the premature ventricular contraction and the QRS complex of the underlying rhythm.
gag reflex A normal neural response triggered by touching the soft palate or posterior pharynx.
gait A manner of walking or moving on foot.
gallbladder A pear-shaped excretory sac on the visceral surface of the right lobe of the liver; it serves as a reservoir for bile.
gallows humor Morbid or cynical humor.
ganglia A group of nerve cell bodies in the peripheral nervous system.
gangrene Dead or dying body tissues attributable to blood supply that is lost or inadequate.
gangrenous Necrosis or death of tissue.
gap junction A small channel between cells that allows the passage of ions and small molecules between cells.
gastric gland A gland located in the stomach mucosa.
gastric lavage Irrigation of the stomach with sterile water or normal saline.
gastrin A polypeptide hormone that stimulates the flow of gastric juice and contributes to the stimulus that causes bile and pancreatic enzyme secretion.
gastritis Inflammation of the lining of the stomach; it may be acute or chronic.
gastroenteritis The inflammation of the stomach and intestines that accompanies numerous gastrointestinal disorders.
gastroesophageal reflux disease A condition in which the stomach contents leak backward from the stomach into the esophagus.
gastrointestinal Of or pertaining to the organs of the gastrointestinal tract from the mouth to the anus.
gastrointestinal decontamination The use of medical methods to empty the stomach of ingested toxins to prevent absorption.
gastrostomy An artificial opening into the stomach.
gating protein A protein that controls the rate at which ions move through an ion channel.
general gas law The characteristic of gas that it flows from an area of higher pressure or concentration to an area of lower pressure or concentration; also known as *Boyle's law*.
general impression An immediate assessment of the environment and the patient's chief complaint used to determine if the patient is ill or injured and the nature of the illness or the mechanism of injury.
generalized seizure A seizure without an identifiable focus in the brain.
generic name The official, established name assigned to a drug.
genitalia Reproductive organs.
genitourinary Of or pertaining to the genital and urinary systems of the body, the organ structures, the organ functions, or both.
genitourinary system Refers to the genital organs and reproductive systems.
German measles See *rubella*.
gerontology The study of the problems of all aspects of aging.
gestation The period from fertilization of the ovum until birth.
gestational diabetes mellitus A disorder characterized by impaired ability to metabolize carbohydrates, usually caused by a deficiency of insulin; it occurs in pregnancy and disappears after delivery but in some cases returns years later.
gingiva The portion of the oral mucosa surrounding the tooth.
gingival hypertrophy Swelling of the gums; it often is associated with chronic phenytoin therapy.
gingivostomatitis Multiple, painful ulcers on the gums and mucous membranes of the mouth; the result of a herpesvirus infection.
Glasgow Coma Scale A standardized system for assessing the degree of conscious impairment in the critically ill and for predicting the duration and ultimate outcome of coma.
glaucoma A condition in which intraocular pressure increases and causes damage to the optic nerve.
glia limitans A supporting structure of nervous tissue consisting of large, star-shaped cells.
gliding joint See *plane joint*.
globule A small, spherical mass.
globulin One of a broad category of simple proteins classified by solubility, mobility, and size.
glomerular filtration rate The amount of plasma that filters into Bowman's capsule per minute.
glomerulus The mass of capillary loops at the beginning of each nephron.
glossopharyngeal nerve Either of a pair of cranial nerves essential to the sense of taste, to sensation in some viscera, and to secretion from certain glands; cranial nerve IX.

glossopharyngeal neuralgia Irritation of the ninth (IX) cranial nerve.

glottic opening The vocal cords and the space between them.

glottis The space between the vocal cords.

glucagon A hormone produced by the alpha cells in the islets of Langerhans that stimulates the conversion of glycogen to glucose in the liver.

glucocorticoid An adrenocortical steroid hormone that increases glyconeogenesis, exerts an antiinflammatory effect, and influences many body functions.

gluconeogenesis The formation of glycogen from fatty acids and proteins rather than carbohydrates.

glucosuria The abnormal presence of glucose in the urine resulting from large amounts of carbohydrates, from kidney disease, or from a metabolic disease such as diabetes mellitus.

gluteus medius muscle The muscle that originates between the anterior and posterior gluteal lines of the ilium and inserts into the greater trochanter of the femur.

glycogenolysis The breakdown of glycogen to glucose.

glycolysis An anaerobic process during which glucose is converted to pyruvic acid.

glycoprotein Any of a large group of conjugated proteins in which the nonprotein substance is a carbohydrate.

goblet cell One of the many specialized cells that secrete mucus and form glands of the epithelium of the stomach, intestine, and parts of the respiratory tract.

goiter A hypertrophic thyroid gland, usually evident as a pronounced swelling in the neck.

golden hour The critical period during which surgical intervention for a trauma patient can enhance survival and reduce complications.

Golgi apparatus Specialized endoplasmic reticulum that concentrates and packages materials for secretion from the cell.

gomphosis An articulation by the insertion of a conic process into a socket, such as the insertion of the root of a tooth into an alveolus of the mandible or maxilla.

gonad A gamete-producing gland, such as an ovary or testis.

gonorrhea A sexually transmitted disease that results from contact with the causative organism *Neisseria gonorrhoeae.*

gout A disease associated with an inborn error of uric acid metabolism that increases production of or interferes with excretion of uric acid; also known as *hyperuricemia.*

gouty arthritis A type of arthritis caused by excess concentration of uric acid, which is converted to sodium urate crystals that are deposited in the joints.

graafian follicle See *vesicular follicle.*

grain The smallest unit of mass in apothecary weights; equal to about 65 mg.

gram A metric unit of mass equal to $\frac{1}{1000}$ of a kilogram.

gram-negative sepsis Sepsis caused by gram-negative bacteria when the bacteria die and are broken down in the body.

grand mal seizure A seizure characterized by a generalized involuntary muscular contraction and cessation of respiration followed by tonic and clonic spasms of the muscles.

grand multipara A woman who has had seven or more deliveries.

granulosa cell A cell in the layer surrounding the primary follicle.

Graves disease A type of excessive thyroid activity characterized by generalized enlargement of the thyroid gland (goiter), which leads to a swollen neck and, often, protruding eyes (exophthalmos).

gravida The number of all current and past pregnancies.

gray matter The gray tissue that makes up the inner core of the spinal column.

great vessels The large arteries and veins entering and leaving the heart; they include the aorta, the pulmonary arteries and veins, and the superior and inferior venae cavae.

groups Subdivisions of the incident command system that encompass specific functional areas of responsibility as deemed necessary by the incident commander.

growth hormone A polypeptide hormone produced and secreted by the anterior pituitary gland; acts as an insulin antagonist.

growth plate The site of bone elongation; also known as the *epiphyseal plate.*

Guillain-Barré syndrome A rare disease that affects the peripheral nervous system, especially the spinal nerves, but also the cranial nerves; it is associated with a viral infection or immunization.

habituation See *drug dependence.*

hair follicle An invagination of the epidermis into the dermis that contains the root of the hair and receives the ducts of sebaceous and apocrine glands.

hair papilla A small, cup-shaped cluster of cells located at the base of the follicle where hair growth begins.

hair root The part of the hair that lies hidden in the follicle.

hair shaft The visible part of the hair.

half duplex The use of two different frequencies, one to transmit and one to receive, that cannot be used simultaneously.

half-life The amount of time required to reduce a drug level to one half its initial value.

hallucinations The apparent perception of sights, sounds, and other sensory phenomena that are not actually present.

Hantavirus A cause of several different forms of hemorrhagic fever with renal syndrome.

hard palate The floor of the nasal cavity that separates the nasal cavity from the oral cavity.

hazard control The phase of rescue that includes managing, reducing, and minimizing risks from

uncontrollable hazards; ensuring scene safety; and providing personal protective equipment that is appropriate for the incident.

head lice Tiny parasites that concentrate around the scalp (sometimes including the eyebrows and eyelashes).

head of bone An eminence on a bone by which it articulates with another bone.

heart The muscular, cone-shaped organ that pumps blood throughout the body by coordinated nerve impulses and muscular contractions.

heart murmur An abnormal heart sound caused by altered blood flow into a chamber or through a valve.

heat cramps Brief, intermittent, and often severe muscular cramps that frequently occur in muscles fatigued by heavy work or exercise.

heat exhaustion A form of heat illness characterized by minor aberrations in mental status, dizziness, nausea, headache, and mild to moderate increase in core body temperature.

heat stroke A syndrome that occurs when the thermoregulatory mechanisms normally in place to meet the demands of heat stress break down entirely. As a result, the body temperature increases to extreme levels. Multisystem tissue damage and physiological collapse also occur.

hemasite A small, button-shaped indwelling vascular device usually placed in the upper arm or proximal, anterior thigh; it is similar to an arteriovenous graft but has an external rubber septum sutured to the skin through which a dialysis catheter is inserted for treatment.

hematemesis Vomiting of bright red blood, indicating upper gastrointestinal bleeding.

hematochezia The passage of red blood through the rectum.

hematology The scientific study of blood and blood-forming tissues.

hematoma A closed injury characterized by blood vessel disruption and swelling beneath the epidermis.

hematoma formation The collection of blood or fluids at the site of injection or cannulation.

hematuria The abnormal presence of blood in the urine.

hemiblock Failure in conduction of the cardiac impulse in either of two main divisions of the left branch of the bundle of His; interruption may occur in the anterior (superior) or posterior (inferior) division.

hemifacial spasm A neuromuscular disorder characterized by frequent involuntary contractions of the muscles on one side of the face.

hemiparesis One-sided weakness.

hemiplegia Paralysis of one side of the body.

hemitransection A cut across the long axis of tissue, such as the spinal cord.

hemoagglutinin An agglutinin that clumps red blood corpuscles.

hemochromatosis A disease of iron metabolism characterized by excess deposition of iron throughout the body.

hemodialysis A procedure in which impurities or wastes are removed from the blood; it is used in treating renal insufficiency and various toxic conditions.

hemodilution The dilution of the blood of elements.

hemoglobin A complex protein-iron compound in the blood that carries oxygen to the cells from the lungs and carbon dioxide away from the cells to the lungs.

hemolysis The breakdown of red blood cells and the release of hemoglobin.

hemolytic anemia A condition in which delivery of oxygen to tissues is reduced because of an increase in hemolysis of erythrocytes.

hemopericardium An accumulation of blood within the pericardial sac surrounding the heart.

hemoperitoneum The presence of extravasated blood in the peritoneal cavity.

hemophilia A group of hereditary bleeding disorders in which one of the factors necessary for blood coagulation is deficient.

hemophilia A A condition caused by a deficiency of coagulation factor VIII; it is considered the classic type of hemophilia.

hemophilia B A condition caused by a deficiency of coagulation factor IX.

hemopneumothorax See *pneumohemothorax*.

hemopoietic tissue Tissue related to the process of formation and development of various types of blood cells.

hemoptysis Coughing up of blood from the respiratory tract.

hemorrhage Flowing of blood.

hemorrhagic shock Hypoperfusion associated with the sudden and rapid loss of significant amounts of blood.

hemorrhagic stroke A stroke (cerebrovascular accident [CVA]) that is caused by bleeding.

hemorrhoids Swollen, distended veins (internal, external, or both) in the rectoanal area.

hemostasis The cessation of bleeding by mechanical or chemical means or by substances that arrest the blood flow.

hemostatic An agent that reduces bleeding by speeding clot formation.

hemothorax The accumulation of blood in the pleural space caused by bleeding from the lung parenchyma or damaged vessels.

hemotympanum Blood behind the tympanic membrane from fractures of the temporal bone.

heparin A substance that inhibits blood clotting; it is obtained from the liver.

heparin lock A peripheral vascular access device that has no attached intravenous tubing; it is used to ensure ready access to peripheral veins for brief administration of medications or when frequent intravenous therapy is indicated on an outpatient basis (e.g., chemotherapy).

hepatic artery The branch of the aorta that delivers blood to the liver.

hepatic encephalopathy A type of brain damage caused by liver disease and consequent ammonia intoxication.

hepatic portal system The system that transports blood from the digestive tract to the liver.

hepatitis An inflammatory condition of the liver characterized by jaundice, hepatomegaly, anorexia, abdominal and gastric discomfort, abnormal liver function, clay-colored stools, and dark urine. Viruses responsible for hepatitis are *hepatitis A virus, hepatitis B virus, hepatitis C virus, hepatitis D virus,* and *hepatitis E virus*.

hepatitis A Viral hepatitis. See *hepatitis.*

hepatitis B Serum hepatitis. See *hepatitis.*

hepatitis C Non-A/non-B hepatitis. See *hepatitis.*

hepatomegaly Enlargement of the liver.

hereditary hemochromatosis An inherited condition in which the body absorbs and stores too much iron. The extra iron accumulates in several organs, especially the liver, heart, and pancreas.

Hering-Breuer reflex A reflex in which afferent impulses from stretch receptors in the lungs arrest inspiration; expiration then occurs; inflation and deflation reflexes triggered to prevent overinflation of the lungs.

hernia Protrusion of any organ through an abdominal opening in the muscle wall of the cavity that surrounds it.

herniated disk Occurs when all or part of a spinal disk is forced through a weakened part of the disk.

herniation A protrusion of a body organ or portion of an organ through an abnormal opening in a membrane, muscle, or other tissue.

herpes Any of several acute inflammatory viral diseases characterized by the eruption of small blisters on the skin and mucous membranes.

herpes simplex virus type 1 An infection caused by the herpes simplex virus; it tends to occur in the facial area, particularly around the mouth and nose.

herpes simplex virus type 2 An infection caused by the herpes simplex virus; it usually is limited to the genital region.

hertz A unit of frequency equal to 1 cycle per second.

hexaxial reference system The system of intersecting lines of the standard limb leads and three other intersecting lines of reference: aV_R, aV_L, and aV_F leads.

hiatal hernia An anatomical abnormality in which part of the stomach protrudes through the diaphragm and up into the chest.

Hickman catheter A long indwelling catheter sometimes used by patients with cancer, gastrointestinal dysfunction, or debilitating disease and by those who need intermittent intravenous administration of antibiotics, nutritional supplements, or other intravenous medications.

high angle An environment in which rescuers need to be secured with rope for safety. The majority of the rescue load is supported by the rope system.

high-altitude cerebral edema The most severe form of acute high-altitude illness. It is characterized by a progression of global cerebral signs in the presence of acute mountain sickness.

high-altitude pulmonary edema A high-altitude illness thought to be caused at least partly by an increase in pulmonary artery pressure that develops in response to hypoxia.

high-grade atrioventricular block Occurs when at least two consecutive atrioventricular impulses (atrial P waves) fail to be conducted to the ventricles.

hilum A depression or pit at the part of an organ where the vessels and nerves enter.

hinge joint A joint that consists of a convex cylinder in one bone applied to a corresponding concavity in another bone; this type of joint allows movement in one plane only.

histamine An amine released by mast cells and basophils that promotes inflammation.

history taking Information gathered during the patient interview.

Hodgkin's disease A malignant disorder characterized by pain and progressive enlargement of lymphoid tissue.

homeopathic Pertaining to homeopathy, a system of therapeutics in which diseases are treated with small doses of drugs that, in larger doses, are capable of producing in healthy persons symptoms like those of the disease to be treated.

homeostasis A state of equilibrium in the body with respect to functions and composition of fluids and tissues.

hordeolum An acute infection of the oil gland; commonly known as a *sty*.

horizontal plane Any place of the erect body parallel to the horizon; dividing the body into upper and lower parts.

hormone A substance, usually a peptide or steroid, produced by one tissue and conveyed by the bloodstream to another tissue or organ to effect physiological activity, such as growth or metabolism.

hormone receptor A receptor on target organs and body tissues that is able to respond to a particular hormone.

host The human or animal exposed to an infectious agent.

host susceptibility Factors of the host that contribute to prevention or continuation of infection.

household system A common system of measure that includes the *glass, cup, tablespoon, teaspoon, drop, quart,* and *pint*.

human immunodeficiency virus The viral agent responsible for acquired immunodeficiency syndrome.

humerus The largest bone of the upper arm, consisting of a body, head, and condyle.

humoral immunity One of the two forms of immunity that respond to antigens such as bacteria and foreign tissue.

Huntington's disease A rare, hereditary disease characterized by quick, involuntary movements, speech disturbances, and mental deterioration; it is caused by degenerative changes in the cerebral cortex and basal ganglia; also known as *Huntington's chorea*.

hyaline cartilage Gelatinous, glossy cartilage tissue; it thinly covers the articulating ends of bones, connects the ribs to the sternum, and supports the nose, trachea, and part of the larynx.

hydrocele A fluid-filled sac along the spermatic cord within the scrotum.

hydrocephalus A pathological condition characterized by an abnormal accumulation of cerebrospinal fluid, usually under increased pressure, within the cranial vault, resulting in dilation of the ventricles.

hydrochloric acid The acid in gastric juice.

hydrogen ion The acidic element in a solution.

hymen A mucous membrane that may partly or entirely occlude the vaginal outlet.

Hymenoptera A large, highly specialized order of insects that includes wasps, bees, and ants.

hyoid bone The U-shaped bone between the mandible and the larynx.

hyperbilirubinemia Larger than normal amounts of the bile pigment bilirubin in the blood, often characterized by jaundice, anorexia, and malaise.

hypercalcemia A higher than normal concentration of calcium in the blood.

hypercholesterolemia Increased serum cholesterol level.

hypercoagulability A tendency of the blood to coagulate more rapidly than normal.

hyperglycemia A greater than normal amount of glucose in the blood.

hyperkalemia A higher than normal concentration of potassium in the blood.

hyperkaluria A high potassium concentration in the urine.

hyperlipidemia An excess of lipids in the plasma.

hypermagnesemia A higher than normal concentration of magnesium in the blood.

hypernatremia A greater than normal concentration of sodium in the blood.

hypernatremic dehydration The loss of more water than sodium.

hyperosmolar hyperglycemic nonketotic syndrome A diabetic state in which the level of ketone bodies is normal. It is caused by hyperosmolarity of extracellular fluid and results in dehydration of intracellular fluid.

hyperparathyroidism A condition of increased parathyroid function.

hyperphosphatemia High levels of alkaline phosphate in the blood.

hyperplasia An excessive increase in the number of cells.

hyperpolarization An increase in the charge difference across the cell membrane; it causes the charge difference to move away from 0 mV.

hypersensitivity reaction An altered immunological response to an antigen that results in a pathological immune response upon reexposure.

hypersomnia Excessive drowsiness; a sleep disorder of excessive depth or duration.

hypertension A disorder characterized by elevated blood pressure, which persistently exceeds 140/90 mm Hg.

hypertensive crisis A sudden, severe increase in blood pressure greater than 200/120 mm Hg.

hypertensive encephalopathy A set of symptoms—including headache, convulsions, and coma—that result solely from elevated blood pressure.

hyperthermia Abnormal elevation of body temperature.

hyperthyroidism A condition characterized by increased activity of the thyroid gland.

hypertonic A term used to describe a solution that causes cells to shrink.

hypertonic solutions Solutions that have higher osmotic pressure than that of body cells.

hypertrophy An increase in the size of a cell.

hyperuricemia See *gout*.

hyperventilation syndrome Abnormally deep or rapid breathing that results in excessive loss of carbon dioxide (producing respiratory alkalosis).

hyphema A hemorrhage into the anterior chamber of the eye; it usually is a result of blunt trauma.

hypocalcemia A lower than normal concentration of calcium in the blood.

hypocarbia A state of diminished carbon dioxide in the blood; also known as *hypocapnia*.

hypochlorhydria A deficiency of hydrochloric acid in the gastric juice of the stomach.

hypoglycemia A lower than normal amount of glucose in the blood.

hypokalemia A lower than normal concentration of potassium in the blood.

hypomagnesemia A lower than normal concentration of magnesium in the blood plasma.

hyponatremia A lower than normal concentration of sodium in the blood.

hyponatremic A term describing a lower than normal concentration of sodium in the blood.

hyponatremic dehydration The loss of more sodium than water.

hypoparathyroidism A condition of diminished parathyroid function.

hypoperfusion Severely inadequate circulation that results in insufficient delivery of oxygen and nutrients necessary for normal tissue and cellular function. Also known as *shock*.

hypophosphatemia Low levels of alkaline phosphate in the blood.

hypopituitarism An abnormal condition caused by diminished activity of the pituitary gland; it is marked by excessive deposits of fat or acquisition of adolescent characteristics.

hypopyon An accumulation of pus in the anterior chamber of the eye.

hypotension An abnormal condition in which the blood pressure is not adequate for normal perfusion and oxygenation of the tissues.

hypothalamus A portion of the diencephalon of the brain that activates, controls, and integrates the peripheral autonomic nervous system, endocrine processes, and many somatic functions such as body temperature, sleep, and appetite.

hypothermia An abnormal body temperature below 95° F (35° C).

hypothyroidism A condition characterized by decreased activity of the thyroid gland.

hypotonia A condition of diminished tone or tension that may involve any body structure.

hypotonic A term used to describe a solution that causes cells to swell.

hypotonicity of the muscles Decreased muscle tone or tension.

hypovolemia An abnormally low circulating blood volume.

hypovolemic shock A form of shock most frequently caused by hemorrhage but also caused by dehydration.

hypoxemia A state of decreased oxygen content of arterial blood.

hypoxia A state of decreased oxygen content at the tissue level.

hypoxic drive The low arterial oxygen pressure stimulus to respiration that is mediated through the carotid bodies.

hysterectomy The surgical removal of the uterus.

iatrogenic Caused by treatment or diagnostic procedures.

identical twins Two offspring born of the same pregnancy and developed from a single fertilized ovum that splits into equal halves during the early phase of embryonic development, giving rise to separate fetuses.

idiopathic Arising from an obscure or unknown cause.

idiopathic epilepsy See *primary epilepsy*.

idiosyncrasy An abnormal or peculiar response to a drug.

idioventricular rhythm A ventricular escape rhythm that results when impulses from higher pacemakers fail to reach the ventricles or when the rate of discharge of higher pacemakers becomes less than that of the ventricles.

IgA Immunoglobulin A is an antibody that plays a crucial role in mucosal immunity.

IgD Immunoglobulin D is an antibody that is present on the surface of most, but not all, B cells, early in their development; signals B cells to be activated.

IgE Immunoglobulin E is an antibody that plays an important role in allergies; especially associated with type I anaphylactic reactions.

IgG Immunoglobulin G is the most abundant antibody; equally distributed in blood and tissue liquids.

IgM Immunoglobulin M is a basic antibody that produces B cells; the first antibody to appear in response to initial exposure to an antigen.

ileocecal sphincter The valve between the ilium of the small intestine and the cecum of the large intestine.

ileostomy A surgical opening into the small intestine.

ileum The distal portion of the small intestine.

ileus An obstruction of the intestines.

iliac crest The upper free margin of the ilium of the hipbone.

iliac spine A portion of the iliac crest; the flaring portion of the hipbone.

ilium One of the three bones that make up the innominate bone.

immersion hypothermia Hypothermia from immersion in cold water.

immune response A defense function of the body that produces antibodies to destroy invading antigens and malignancies.

immune system A complex network of cells, tissues, and organs that work together to protect the body against "attacks" by foreign substances.

immunity Insusceptibility to a particular disease or condition.

immunization The process of rendering a person immune or of becoming immune.

immunogen Any agent or substance capable of an immune response or of producing immunity.

immunoglobulin Any of five structurally and antigenically distinct antibodies present in the serum and external secretions of the body; they are IgA, IgD, IgE, IgG, and IgM.

immunologic memory The ability to rapidly produce large quantities of specific immune cells after subsequent exposure to a previously encountered antigen.

immunology A broad branch of medical science that covers the study of the immune system.

immunosuppression The reduction in the activation or efficiency of the immune system often caused by drugs or radiation in order to prevent the rejection of grafts or transplanted tissues or to control autoimmune disease.

implied consent The presumption that an unconscious or incompetent person would consent to lifesaving care.

impulse control disorders A group of psychiatric conditions characterized by the inability to resist an impulse or a temptation to perform some act that is unlawful, socially unacceptable, or self-harmful.

inadvertent hyperventilation Excessive ventilation is thought to result in increased intrathoracic pressure and decreased coronary perfusion pressure; also known as *rescuer hyperventilation*.

incident command system A management program designed to control, direct, and coordinate emergency response operations and resources.

incomplete abortion An abortion in which the patient has passed some but not all of the products of conception.

incomplete breech The presentation that occurs when the fetus has one or both hips incompletely flexed, resulting in the presentation of one or both lower extremities, often a foot.

incontinence The inability to control bladder or bowel function.

incubation period The stage of infection during which an organism reproduces; it begins with invasion of an agent and ends when the disease process begins.
incus The middle of the three ossicles in the middle ear.
indigenous flora Agents found on various sites of the body that could produce disease if allowed access to the interior of the body.
induced abortion The intentional termination of a pregnancy.
infant A child 28 days to 1 year of age.
infarction Cell death.
infectious disease Any illness that is caused by a specific microorganism.
infectious pericarditis Inflammation of the pericardium associated with infection.
inferior Toward the feet; below a point of reference in the anatomical position.
inferior nasal concha One of three bony ridges on the lateral wall of the nasal cavity.
inferior vena cava The vein that returns blood from the lower limbs and the greater part of the pelvic and abdominal organs to the right atrium.
infertility The inability to produce offspring.
infiltration The process whereby a fluid passes into tissues.
inflammatory myopathies A group of diseases that involve chronic muscle inflammation accompanied by muscle weakness.
inflammatory response A tissue reaction to injury or an antigen; it may include pain, swelling, itching, redness, heat, and loss of function.
influenza A highly contagious infection of the respiratory tract transmitted by airborne droplet infection. Researchers have identified three main types of the virus (types A, B, and C).
informed consent Consent obtained from a patient after explaining all facts necessary for the patient to make a reasonable decision.
inguinal canal The passage through the lower abdominal wall that transmits the spermatic cord in the male and the round ligament in the female.
inguinal node One of approximately 18 nodes in the group of lymph glands in the upper femoral triangle of the thigh.
inhalation injury An upper and/or lower airway injury that results from thermal and/or chemical exposure.
initial assessment A component of the patient assessment to recognize and manage all immediate life-threatening conditions.
injury risk Real or potentially hazardous situations that put individuals at increased risk for sustaining an injury.
injury surveillance The ongoing systematic collection, analysis, and interpretation of injury data essential to the planning, implementation, and evaluation of public health practice.
inner ear The part of the ear that contains the sensory organs for hearing and balance.
inotropic Pertaining to the force or energy of muscle contraction, particularly contractions of the heart.
insertion The more movable attachment point of a muscle.
insomnia A chronic inability to sleep or to remain asleep throughout the night.
inspection A visual assessment of the patient and surroundings.
inspiration The act of drawing air into the lungs.
inspiratory capacity The sum of the tidal volume and the inspiratory reserve volume.
inspiratory center The region of the medulla that stimulates inspiration.
inspiratory reserve volume The maximum volume of air that can be inspired after a normal inspiration.
insulin A hormone secreted by the pancreatic islets.
integumentary system The largest organ system in the body, consisting of the skin and accessory structures.
interatrial septum Tissue that separates the right and left atria of the heart.
intercalated disk Cell-to-cell attachment with gap junctions between cardiac muscle cells.
intercellular Occurring between or among cells.
intercostal muscles Internal and external muscles between the ribs that contract to raise the ribs, thereby increasing the front-to-back (anterior-posterior) and side-to-side dimensions of the chest cavity.
interference Any undesired radio signal on a radio frequency. It may arise from other radio transmitters or other sources of electromagnetic radiation. "Nuisance interference" is interference that can be heard but does not override system signals. "Destructive interference" overrides system signals.
internal anal sphincter A sphincter muscle located at the caudal end of the rectum.
internal barriers Protection against germs provided by the inflammatory response and the immune response; the body's second line of defense against infection.
internal carotid artery Each of two arteries that enter the cranial vault through the carotid canals.
internal jugular vein One of a pair of veins in the neck; each collects blood from one side of the brain, the face, and the neck, and both unite with the subclavian vein to form the brachiocephalic vein.
internal mammary artery One of the pair of arteries that arise from the first portions of the subclavian arteries; it supplies the pectoral muscles, breasts, pericardium, and abdominal muscles; also known as the *internal thoracic artery*.
internal respiration The transfer (diffusion) of oxygen and carbon dioxide between the capillary red blood cells and the tissue cells.
internal thoracic artery See *internal mammary artery*.
internal urinary sphincter The smooth muscle of the bladder located at the junction of the urethra with the urinary bladder; it controls the flow of urine through the urethra.

interneuron See *motor neuron*.
internodal tract Pathways between the segments of a nerve fiber.
interpolated premature ventricular complex A premature ventricular contraction that falls between two sinus beats without interrupting the rhythm.
interstitial fluid Fluid that occupies the space outside the blood vessels and/or outside of cells of an organ or tissue.
interventricular foramen One of two passageways between the two lateral ventricles and the third ventricle.
interventricular septum The tissue that separates the right and left ventricles of the heart.
intervertebral disk One of the fibrous disks between all adjacent spinal vertebrae except the atlas and axis; it serves as a shock absorber for the vertebral column and provides additional support for the body; it also prevents the vertebral bodies from rubbing against each other.
intracellular Occurring within cell membranes.
intracellular fluid The fluid found in all body cells.
intracerebral hematoma An accumulation of blood or fluid within the tissue of the brain.
intracranial pressure The pressure inside the skull, brain tissue, and cerebrospinal fluid.
intradermal injection The introduction of a substance (e.g., serum or vaccine) with a hypodermic needle into the dermis.
intramuscular injection The introduction of medication with a hypodermic needle into muscle.
intraocular pressure Pressure within the eye that keeps the eye inflated.
intraosseous infusion Placement of a rigid needle into a bone and the infusion of fluid and medication directly into the bone marrow.
intraosseous injection The introduction of medication or fluid into the bone marrow.
intrapartum The period during labor and delivery.
intrapleural Within the pleura.
intrapleural pressure See *intrathoracic pressure*.
intrapulmonic pressure The pressure of the gas within the alveoli.
intrarenal disease Refers to disease or damage within the kidney.
intrathecal injection The introduction of medication with a hypodermic needle into the subarachnoid space.
intrathoracic pressure The pressure in the pleural space; also known as *intrapleural pressure*.
intravenous injection The introduction of medication with a hypodermic needle into a vein.
intrinsic factor The factor secreted by the parietal cells of the gastric glands; it is required for adequate absorption of vitamin B_{12}.
invagination Infolding or in-pocketing.
invasion of privacy Making public, without legal justification, details about a person's private life that might reasonably expose that person to ridicule, notoriety, or embarrassment.
inversion Turning inward.
involuntary Occurring without conscious control or direction.
involuntary consent Treatment that is granted by authority of law.
involuntary guarding An unconscious rigid contraction of the abdominal muscles; a sign of peritoneal inflammation.
involuntary muscle A muscle that is not normally consciously controlled; see *smooth muscle*.
ion An atom or group of atoms carrying a charge of electricity by virtue of having gained or lost one or more electrons.
ipsilateral Pertaining to the same side of the body.
iris The colored contractile membrane of the eye that can be seen through the cornea.
iritis Inflammation of the iris of the eye.
iron deficiency anemia Anemia caused by inadequate supplies of iron needed to synthesize hemoglobin.
irregular bones Bones that are not representative of the other three categories (long, short, or flat bones); examples include vertebrae and facial bones.
irreversible shock A stage of shock that results in cellular ischemia and necrosis and subsequent organ death, even with oxygenation and perfusion restored.
ischemia A state of insufficient perfusion of oxygenated blood to a body organ or part.
ischium One of the three parts of the hipbone, which joins the ilium and the pubis to form the acetabulum.
islets of Langerhans Clusters of cells within the pancreas that produce insulin, glucagon, and pancreatic polypeptide.
isoimmunity An immune response directed against beneficial foreign tissues.
isolette A self-contained incubator unit that provides controlled heat, humidity, and oxygen for the isolation and care of premature and low-birth-weight neonates.
isometric contraction A muscle contraction in which the length of the muscle does not change, but the tension produced increases.
isotonic A term used to describe a solution that causes cells neither to shrink nor to swell.
isotonic contraction A muscle contraction in which the tension produced by the muscle stays the same, but the muscle length becomes shorter.
isotonic dehydration Excessive loss of sodium and water in equal amounts.
J point The point at which the T wave takes off from the QRS complex.
jacksonian seizure A transitory disturbance in motor, sensory, or autonomic function resulting from abnormal neuronal discharges in a localized part of the brain; also known as a *focal seizure*.
jaundice A yellow discoloration of the skin, mucous membranes, and sclerae of the eyes caused by a greater than normal amount of bilirubin in the blood.
jejunum One of the three portions of the small intestine.

joint Any one of the connections between bones that are classified according to structure and movability as fibrous, cartilaginous, or synovial. *Fibrous joints* are immovable, *cartilaginous joints* are slightly movable, and *synovial joints* are freely movable.

joint capsule A well-defined structure that encloses a joint.

joint dislocation An injury that occurs when the normal articulating ends of two or more bones are displaced.

joint disorder Any disease or injury that affects human joints.

Joule's law The principle that the amount of heat produced is directly proportional to the square of the current strength times the resistance of the tissue times the duration of the current flow.

jugular notch The superior margin of the manubrium; it is palpated easily at the anterior base of the neck; also known as the *suprasternal notch.*

jugular vein distention Engorgement of jugular veins caused by an increase in central venous pressure; it is estimated by positioning the head of a supine patient at a 45-degree angle and observing the neck veins.

kallikrein/kinin system A proposed hormonal system that functions within the kidneys, mediating production of bradykinin, which acts as a vasodilator peptide.

Kaposi's sarcoma A malignant, multifocal neoplasm of reticuloendothelial cells that begins as soft, brownish or purple papules on the feet and slowly spreads in the skin, metastasizing to the lymph nodes and viscera; it is associated with diabetes, malignant lymphoma, acquired immunodeficiency syndrome, and other disorders.

Kehr's sign Pain in the left shoulder thought to be caused by referred pain secondary to irritation of the adjacent diaphragm.

Kent fibers See *bundle of Kent*.

keratitis Any inflammation of the cornea.

ketoacidosis Acidosis accompanied by the accumulation of ketones in the body, resulting from faulty carbohydrate metabolism.

ketoacids Compounds containing the carbonyl and carboxyl groups.

ketogenesis The formation or production of ketone bodies.

ketone bodies The normal metabolic products of lipids and pyruvate within the liver; excessive production leads to their excretion in urine.

ketonuria Presence in the urine of excessive amounts of ketone bodies.

kidney The organ that cleanses the body of the waste products continually produced by metabolism.

kilogram A metric unit of mass equal to 1000 grams or 2.2046 pounds.

kilohertz A unit of frequency equal to 1000 cycles per second.

kinematics The process of predicting injury patterns that can result from the forces and motions of energy.

kinin Serum protein that causes vasodilation and increases vascular permeability.

KKK standards The national standards that provide the foundation of uniformity among ambulance vehicles.

Koplik's spots Small red spots with bluish white centers on the lingual and buccal mucosa, characteristic of measles.

Korsakoff's psychosis A form of amnesia often seen in alcoholics, characterized by a loss of short-term memory and an inability to learn new skills.

Krebs cycle A sequence of enzymatic reactions involving the metabolism of carbon chains of sugar, fatty acids, and amino acids to yield carbon dioxide, water, and high-energy phosphate bonds.

Kussmaul's respiration An abnormally deep, rapid sighing respiratory pattern characteristic of diabetic ketoacidosis or other metabolic acidosis.

kyphosis An abnormal condition of the vertebral column characterized by increased convexity in the curvature of the thoracic spine as viewed from the side.

labia majora Two rounded folds of skin surrounding the labia minora and the vestibule.

labia minora Two longitudinal folds of mucous membrane enclosed by the labia majora and bounding the vestibule.

labial frenulum A medial fold of mucous membrane connecting the inside of each lip to the corresponding gum.

labyrinthitis An ear disorder that involves irritation and swelling of the inner ear structure called the *labyrinth.*

laceration A torn or jagged wound.

lacrimal bone One of the smallest and most fragile bones of the face; it is located in the anterior part of the medial wall of the orbit.

lacrimal canal The canal that carries excess tears away from the eye.

lacrimal gland The tear gland located in the superolateral corner of the orbit.

lacrimal sac An enlargement of the lacrimal canal that leads into the nasolacrimal duct.

lacrimation Excessive tear production.

lactate A salt of lactic acid.

lactation The secretion of milk from the breasts to nourish an infant or child.

lactic acid A three-carbon molecule derived from pyruvic acid as a product of anaerobic respiration.

lactic acidosis A disorder characterized by an accumulation of lactic acid in the blood, resulting in a lowered pH in muscle and serum.

lactiferous duct The duct that drains the grapelike cluster of milk-secreting glands in the breast.

lactose intolerance A sensitivity disorder resulting in the inability to digest lactose because of a deficiency of or defect in the enzyme lactase.

landing zone An area prepared for the landing of an aircraft; generally 100 by 100 feet.

lanugo hair Soft, downy hair covering a normal fetus.

laparoscopy Examination of the abdominal cavity with a laparoscope.
large intestine The portion of the digestive tract comprising the cecum, the appendix, the ascending, transverse, and descending colons, and the rectum.
laryngectomy Surgical removal of the larynx, performed to treat cancer of the larynx.
laryngitis Inflammation of the larynx.
laryngopharynx The lowest part of the pharynx.
laryngoscope An endoscope for visualization of the larynx.
laryngoscopy Examination of the larynx via a laryngoscope.
laryngotracheobronchitis See *croup*.
larynx The voice box, located just below the pharynx.
late adulthood Persons 61 years of age and older.
latent period A stage of infection that begins when a pathogenic agent invades the body and ends when the agent can be shed or communicated.
latent period of drug action See *onset of action*.
latent TB infection Tuberculosis that is not symptomatic or infectious; must be treated to prevent active TB disease.
lateral malleolus The rounded process on the lateral side of the ankle joint.
lateral recumbent position The position in which the patient is lying on his or her right or left side.
lateral ventricle A large, fluid-filled space in each cerebral hemisphere.
laxative A substance that causes evacuation of the bowel by increasing the bulk of the feces, by softening the stool, or by lubricating the intestinal wall.
lead An electrode sensor attached to the body to record electrical activity, especially of the heart and brain.
leaky capillary syndrome A syndrome that occurs when the capillary lining permits protein-containing fluid to leak into the interstitial spaces.
Le Fort fracture A fracture pattern that can be produced in the midface region.
left anterior descending artery The subdivision of the left coronary artery that supplies the left auricle and its appendix and supplies branches to both ventricles and numerous small branches to the pulmonary artery and commencement of the aorta.
left atrium One of the four chambers in the human heart; receives oxygenated blood from the lungs and pumps it into the left ventricle.
left coronary artery One of a pair of branches from the ascending aorta that supplies both ventricles and the left atrium.
left mainstem bronchus One of two main bronchi that branches from the trachea at the level of the carina.
legend A prescription drug.
legionellosis An acute bacterial pneumonia caused by infection with *Legionella pneumophila;* it is characterized by an influenza-like illness followed within a week by high fever, chills, muscle aches, and headache.
legionnaires' disease See *legionellosis*.
Lenègre's disease See *Lev's disease*.
lens The crystalline portion of the eye.
lethargy A state of indifference, apathy, or sluggishness.
leukemia A malignant neoplasm of blood-forming organs.
leukocyte White blood cell.
leukocytosis An abnormal increase in the number of circulating white blood cells.
leukopenia A decrease in the number of white blood cells (most commonly neutrophils).
leukotrienes A class of biologically active compounds that occur naturally in leukocytes and that produce allergic and inflammatory reactions.
Lev's disease Third-degree block in the elderly from chronic degenerative changes in the conduction system; it usually is not associated with increased parasympathetic tone or drug toxicity; also known as *Lenègre's disease*.
libel Publishing in writing false statements about someone, knowing them to be false, with malicious intent or with reckless disregard for their falsity.
libido The drive associated with sexual desire, pleasure, or creativity.
licensure The process by which a government agency grants permission to an individual to engage in an occupation or profession.
life threat An illness or injury that threatens survival.
ligament A band of white, fibrous tissue that connects bones.
ligamentum arteriosum A fibrous cord from the pulmonary artery to the branch of the aorta; the remains of the ductus arteriosus of the fetus.
limbic system The part of the brain involved with emotions and olfaction.
linear fracture A fracture that extends parallel to the long axis of a bone but does not displace the bone tissue.
lingual tonsil A collection of lymphoid tissue on the posterior portion of the dorsum of the tongue.
lipid Any of the free fatty acid fractions in the blood.
lipid bilayer The central layer of the cytoplasmic membrane; it is composed of a double layer of lipid molecules.
lipodystrophy Any abnormality in the metabolism or distribution of fats.
lipoprotein A conjugated protein in which lipids form an integral part of the molecule; it is synthesized primarily in the liver.
liquefaction Conversion of solid tissues to a fluid or semifluid state.
liter A metric unit of capacity equal to 1 cubic decimeter, 61.025 cubic inches, or 1.0567 liquid quarts.
Littre's gland The inner surface of the membrane lining the urethra.
liver An organ in the upper abdomen that aids in digestion and removes waste products and cellular debris from the blood; the largest solid organ in the human body.
loading dose A large quantity of drug that temporarily exceeds the capacity of the body to excrete the drug.
lobule A small lobe or subdivision of a lobe.

long bones Bones that are longer than they are wide, such as the humerus, ulna, radius, femur, tibia, fibula, and phalanges.

long saphenous vein See *saphenous vein*.

loop diuretic A group of powerful, short-acting agents that inhibit sodium and chloride reabsorption in the loop of Henle, resulting in an excessive loss of potassium and water and an increase in the excretion of sodium.

loop of Henle The U-shaped portion of the renal tubule.

lordosis An inward curvature in the lumbar spine that is normally present to some degree.

low angle An environment in which the weight of the stretcher is supported primarily by the tender's legs, but rope systems are required to facilitate movement and for fall protection.

lower airway Airway structures below the glottis.

lower esophageal sphincter The ring of muscle located at the inferior end of the esophagus that regulates the passage of materials out of the esophagus.

lucid interval A period of relative mental clarity between periods of decreased consciousness or irrationality.

Ludwig's angina A type of cellulitis that involves inflammation of the tissues of the floor of the mouth, under the tongue.

lumbar vertebrae The five largest segments of the movable part of the vertebral column; they are designated L1 to L5.

lumbosacral plexus The combination of all the ventral primary divisions of the lumbar, sacral, and coccygeal nerves.

lumen A cavity or channel within any organ or structure of the body.

Lund and Browder chart A method to estimate burn injury that assigns specific numbers to each body part and that accounts for developmental changes in percentages of body surface area.

lung One of a pair of light, spongy organs in the thorax; the main component of the respiratory system.

lung cancer A disease of uncontrolled cell growth in tissues of the lung.

lunula The crescent-shaped white area of the nail; it is most visible on the thumbnail.

luxation A complete dislocation.

Lyme disease An acute, recurrent inflammatory infection transmitted by a tick.

lymph node An encapsulated mass of lymph tissue found among lymph vessels.

lymph nodule Any of the small, densely packed spherical nodes or aggregations of lymph cells embedded in the reticular meshwork of the lymphatic system; found mainly in the tonsils, spleen, and thymus.

lymphangitis An inflammation of one or more lymphatic vessels.

lymphatic system The network of vessels, ducts, nodes, valves, and organs involved in protecting and maintaining the internal fluid environment of the body.

lymphocyte A type of white blood cell formed in lymphoid tissue.

lymphokine One of the chemical factors produced and released by T lymphocytes that attract macrophages to the site of infection or inflammation.

lymphoma A group of diseases that range from slowly growing chronic disorders to rapidly evolving acute conditions.

lyse To cause decomposition.

lysis The process by which a cell swells and ruptures.

lysosome A membranous-walled organelle that contains enzymes, which enable it to function as an intracellular digestive system.

macrodrip tubing An apparatus used to deliver measured amounts of intravenous solutions at specific flow rates based on the size of drops of the solution. The drops delivered by a macrodrip are larger than those delivered by a microdrip.

macromolecule A molecule of colloidal size, such as a protein, nucleic acid, or polysaccharide.

macrophage A phagocytic cell in the immune system.

macula A small pigmented area that appears separate or different than the surrounding tissue.

maintenance dose The amount of a drug required to keep a desired steady state of drug concentration in tissues.

major incident An event for which available resources are insufficient to manage the nature of the emergency.

malaise A vague feeling of weakness or discomfort.

malar eminence The zygomatic bone or cheekbone.

malaria A serious infectious illness caused by one or more of at least four species of the protozoan genus *Plasmodium;* it is characterized by chills, fever, anemia, and an enlarged spleen.

malignant Very dangerous or virulent; likely to cause death; a cancerous tumor that tends to metastasize.

malleolus A rounded, bony process, such as the protuberance on each side of the ankle.

malleus The largest of the three ossicles in the middle ear.

Mallory-Weiss syndrome A condition characterized by massive bleeding after a tear in the mucous membrane at the junction of the esophagus and the stomach.

mamma The breast; the organ of milk secretion.

mammalian diving reflex A reflex triggered by immersing the face in cold water; it diverts blood from the arms and legs to the central circulation and lowers the heart rate as a result of vagal stimulation.

mammary gland An external accessory sex organ in females; breasts.

managed care Patient care services that are provided to members by managed care organizations.

managed care organizations Networks that provide patient care services to their members, including health maintenance organizations and preferred provider organizations.

mandible A large bone that constitutes the lower jaw.

mania A mood disorder characterized by extreme excitement, hyperactivity, agitation, and sometimes violent and self-destructive behavior.

manic Pertaining to a specific psychosis.

manic-depressive disorder See *bipolar disorder*.

manubriosternal junction The point at which the manubrium joins the body of the sternum; the location of the second rib; also known as the *sternal angle*.

manubrium One of the three bones of the sternum; it has a broad, quadrangular shape that narrows caudally at its articulation with the superior end of the body of the sternum.

Marfan syndrome An abnormal condition characterized by elongation of the bones, often with associated abnormalities of the eyes and cardiovascular system.

mass casualty incident An event for which available resources are insufficient to manage the number of casualties.

mast cells Specialized cells of the inflammatory response.

mastectomy Surgical removal of one or both breasts, performed to remove a malignant tumor.

mastication Chewing, tearing, or grinding food with the teeth while it is mixed with saliva.

mastoid air cell One of several spaces within the mastoid process of the temporal bone; it is connected to the middle ear by ducts.

masturbation Sexual stimulation, especially of one's own genitals, often to the point of orgasm.

maxilla One of a pair of large bones that form the upper jaw.

maxillary sinus One of the pair of large air cells that form a pyramidal cavity in the body of the maxilla.

McBurney point A site of extreme sensitivity in acute appendicitis situated in the normal area of the appendix, approximately 2 inches from the right anterior-superior spine of the ilium, on a line between that part of the spine and the umbilicus.

mean arterial pressure The arithmetic mean of the blood pressure in the arterial portion of the circulation.

measles An acute, highly contagious viral disease involving the respiratory tract that is characterized by a spreading, maculopapular, cutaneous rash.

meconium aspiration syndrome Inhalation of meconium by the fetus or newborn; the meconium can block the air passages and result in failure of the lungs to expand or cause other pulmonary dysfunction.

meconium staining The presence of fetal stool in amniotic fluid.

medial malleolus The rounded process on the medial side of the ankle joint.

mediastinitis Inflammation of the mediastinum.

mediastinum A portion of the thoracic cavity in the middle of the thorax between the pleural sacs containing the two lungs; it extends from the sternum to the vertebral column and contains all the thoracic viscera except the lungs.

mediated transport mechanisms Mechanisms that use carrier molecules to move large, water-soluble molecules or electrically charged molecules across cell membranes.

medical asepsis The removal or destruction of disease-causing organisms or infected material.

medical direction A process of ensuring that actions taken on behalf of ill or injured persons are medically appropriate, including prospective, concurrent, and retrospective aspects of emergency medical services quality improvement, hiring, and education.

medulla The lowest part of the brainstem, which controls vital functions; an enlarged extension of the spinal cord; also known as the *medulla oblongata*.

medulla oblongata See *medulla*.

medullary cavity A large, marrow-filled cavity in the diaphysis of a long bone.

megahertz A unit of frequency equal to 1 million cycles per second; emergency medical services radios transmit and receive on frequencies measured in megahertz.

melanocyte A body cell capable of producing melanin.

melatonin The only hormone secreted in the bloodstream by the pineal gland; it lightens skin pigmentation and may inhibit numerous endocrine functions.

melena Abnormal black, tarry stools containing digested blood.

membrane channel A tunnel through which specific molecules may pass.

membrane permeability A quality of cell membranes that permits the passage of solvents and solutes into and out of cells.

membranous labyrinth A membranous structure within the inner ear; it forms the cochlea, vestibule, and semicircular canals.

memory cells Cells that remember the same pathogen for faster antibody production with future exposures; produced by the division of B cells.

menarche The first menstruation and the commencement of the cyclic menstrual function.

Meniere's disease An abnormality of the inner ear that causes vertigo and tinnitus; associated with fluctuations in hearing loss and a sensation of pressure or pain in the affected ear.

meninges Fluid-containing membranes surrounding the brain and spinal cord.

meningitis Inflammation of the meninges.

meningococcal meningitis Inflammation of the membranes that surround the spinal cord and brain; it can be caused by a variety of different bacteria, viruses, and other microorganisms; also known as *spinal meningitis*.

menopause The cessation of menses.

menstruation The periodic discharge through the vagina of a blood secretion containing tissue debris from the shedding of the endometrium from the nonpregnant uterus.

mental illness Any form of psychiatric disorder.

mental retardation A disorder characterized by below-average intellectual function with deficits or impairments in the ability to learn and adapt socially.

mental status examination An evaluation tool that includes an assessment of appearance and behavior, speech and language, emotional stability, and cognitive abilities.

merocrine gland A gland that secretes products with no loss of cellular material, such as a water-producing sweat gland.

mesencephalon See *midbrain*.

mesentery The double layer of peritoneum extending from the abdominal wall to the abdominal viscera; it conveys vessels and nerves.

mesovarium A short peritoneal fold connecting the ovary with the broad ligament of the uterus.

metabolic acidosis A disorder that results when excess acid is added to the body fluids or bicarbonate is lost from them.

metabolic alkalosis A disorder that results from a significant loss of acid in the body or increased levels of the base bicarbonate.

metabolism The culmination of all chemical processes that take place in living organisms.

metabolite A substance that is produced by metabolic action or that is necessary for the metabolic process.

metacarpal One of five bones extending from the carpus to the phalanges.

metaplasia A change from one cell type to another that is better able to tolerate adverse conditions; a conversion into a form that is not normal for that cell.

metarteriole One of the small peripheral blood vessels that contain scattered groups of smooth muscle fibers in their walls; they are located between the arterioles and the true capillaries.

metastasis The movement or spreading of cancer cells from one organ or tissue to distant locations in the body.

metastasize The ability of cancer cells to move or spread from one organ or tissue to distant locations in the body.

metatarsal Any one of the five bones comprising the metatarsus.

meter A metric unit of length equal to 1000 millimeters.

methanol A chemical widely used as a solvent and in the production of formaldehyde.

methemoglobin A form of hemoglobin in which the iron component has been oxidized from the ferrous to the ferric state.

methemoglobinemia The presence of methemoglobin in the blood, causing cyanosis as a result of the inability of the red blood cells to release oxygen.

metric system Units of measurement that include the meter, the liter, and the gram.

microcirculation Refers to circulation of blood from the heart to the arteries, capillaries, and veins.

microdrip tubing An apparatus for delivering relatively small amounts of intravenous solutions at specific flow rates; the drops delivered by a microdrip are smaller than those delivered by a macrodrip.

microgram A metric unit of mass equal to $\frac{1}{1,000,000}$ of a gram.

microinfarct A small infarct caused by obstruction of circulation in capillaries, arterioles, or small arteries.

microorganism Any tiny, usually microscopic entity capable of carrying on living processes, such as bacteria, fungi, protozoa, and viruses.

microthrombus A minute thrombus.

microtubule A hollow tube that helps to support the cytoplasm of the cell; a component of certain cell organelles such as centrioles, spindle fibers, cilia, and flagella.

microwave Radio waves with frequencies of 890 MHz and higher. The signals are generated by special equipment that depends on line of sight placement to operate properly. Microwave channels may have a wide band to carry a large number of simultaneous transmissions.

midbrain One of the three parts of the brainstem; also known as the *mesencephalon.*

middle adulthood Persons 41 to 60 years of age.

middle cerebral artery The artery that supplies a large portion of the lateral cerebral cortex.

middle ear An air-filled space within the temporal bone that contains the auditory ossicles.

migraine A severe, incapacitating headache that often is preceded by visual and/or gastrointestinal disturbances.

milliequivalent A unit of measure equal to $\frac{1}{1000}$ of a gram equivalent.

milligram A metric unit of mass equal to $\frac{1}{1000}$ of a gram.

milliliter A metric unit of capacity equal to $\frac{1}{1000}$ of a liter.

millimeter A metric unit of length equal to $\frac{1}{1000}$ of a meter.

mineral An inorganic substance usually referred to by the name of the compound of which it is a part; minerals are important in regulating many body functions.

mineralocorticoid A hormone secreted by the adrenal cortex that maintains normal blood volume, promotes sodium and water retention, and increases urine secretion of potassium and hydrogen ions.

minim A measure of volume in the apothecary system, originally 1 drop of water; 60 minims equal 1 fluid dram, and 1 minim equals 0.06 mL.

minimal effective concentration The lowest plasma concentration that produces the desired drug effect.

minute alveolar ventilation The amount of inspired gas available for gas exchange during 1 minute.

minute volume The amount of gas inhaled or exhaled in 1 minute. It is found by multiplying the tidal volume by the respiratory rate.

miscarriage See *spontaneous abortion*.

missed abortion The retention of the fetus in utero for 4 or more weeks after fetal death.

mitochondria Small, spherical, rod-shaped, or thin filamentous structures in the cytoplasm of cells; a site of adenosine triphosphate production.

mitosis Cell division resulting in two daughter cells with exactly the same number and type of chromosomes as the mother cell.

mitral valve See *bicuspid valve*.

mitral valve prolapse Protrusion of one or both cusps of the mitral valve back into the left atrium during ventricular systole, resulting in incomplete closure of the valve and mitral insufficiency.

mittelschmerz Abdominal pain in the region of the ovary during ovulation; it usually occurs midway through the menstrual cycle.

MMR vaccine The abbreviation for live measles, mumps, and rubella virus vaccine.

mobile data terminal A computer connected through a modem ("black box") with a radio that sends and receives pretyped messages to printers, computer screens, or both. Some mobile data terminals have graphics (floor plans) and database (hazardous materials) capabilities. Mobile data terminals rely on a host computer interfaced to a base station.

mobile relay station A fixed base station that automatically retransmits mobile or portable radio communications back to the receiving frequency of other portables, mobiles, and base stations operating in the same system; also known as a repeater.

mobile repeater A mobile radio unit capable of automatically retransmitting any radio traffic originated by a hand-held portable, by other mobiles, or by base stations. This repeater may be one-way or two-way and may be known as a PAC-RAT (Motorola) or an extender. Also known as a vehicle repeater.

mode of transmission The way in which diseases are transmitted; may be direct or indirect contact.

mole A standard unit used to measure the amount of a substance.

monocyte A type of white blood cell found in lymph nodes, spleen, bone marrow, and loose connective tissue.

monomorphic Existing only in one form.

mononucleosis A viral infection causing fever, sore throat, and swollen lymph glands, especially in the neck.

mons pubis The prominence caused by a pad of fatty tissue over the symphysis pubis in the female.

mood disorder Refers to changes in emotions that a person experiences in life (e.g., happiness, depression, fear, and anxiety).

morals Social standards or customs; dealing with what is right or wrong in a practical sense.

Moro reflex A normal infant response elicited by a sudden loud noise. The infant flexes the legs, makes an embracing gesture with the arms, and usually gives a brief cry.

morphology The study of the physical shape and size of a specimen, plant, or animal.

motor neuron A neuron that innervates skeletal, smooth, or cardiac muscle fibers; also known as an interneuron.

mucin The chief ingredient in mucus.

mucosa Mucous membrane.

mucus The viscous, slippery secretion of mucous membranes and glands.

multifocal premature ventricular complex A premature ventricular complex that originates from multiple sites in the ventricles.

multigravida A woman who has had two or more pregnancies.

multipara A woman who has had two or more deliveries.

multiple gestation A pregnancy with more than one fetus.

multiple myeloma A malignant neoplasm of the bone marrow.

multiple organ dysfunction syndrome The progressive failure of two or more organ systems after a severe illness or injury.

multiple sclerosis A progressive disease of the central nervous system in which scattered patches of myelin in the brain and spinal cord are destroyed.

multiplex mode A communications mode with the ability to transmit two or more different types of information simultaneously, in either or both directions, over the same frequency.

mumps An acute viral disease characterized by swelling of the parotid glands.

Munchausen syndrome A factitious disorder in which the patient makes routine pleas for treatment and hospitalization for a symptomatic, but imaginary, acute illness.

Munchausen syndrome by proxy A factitious disorder in which a person injures or induces illness in others (usually children) in order to gain sympathy.

Murphy's sign Cessation of inspiration during right upper quadrant examination (may indicate acute cholecystitis).

muscarinic receptor A class of cholinergic receptor molecule specifically activated by muscarine in addition to acetylcholine.

muscle strain A slight tear in a muscle or tendon.

muscle tone The constant tension produced by muscles of the body for long periods of time.

muscular dystrophy An inherited muscle disorder of unknown cause marked by a slow but progressive degeneration of muscle fibers.

muscular system The body system responsible for execution of movement and postural maintenance.

muscular tissue A primary tissue type characterized by its contractile abilities.

musculoskeletal system The body system comprised of bones, muscles, tendons and ligaments, and articulating surfaces (e.g., joints, bursa, disks).

mutagenic Any chemical or physical environmental agent that induces a genetic mutation or increases the mutation rate.

mutual aid An agreement with neighboring emergency agencies to exchange equipment and personnel when necessary.

myalgia Diffuse muscle pain, usually accompanied by malaise; it occurs in many infectious diseases.

myasthenia Muscle weakness.
myasthenia gravis An autoimmune disorder in which muscles become weak and tire easily.
Mycobacterium leprae A genus of gram-positive bacteria that cause leprosy.
Mycobacterium tuberculosis A genus of gram-positive bacteria that cause tuberculosis.
Mycoplasma A genus of microscopic organisms lacking rigid cell walls; they are considered to be the smallest free-living organisms.
mycoplasmal pneumonia A type of atypical pneumonia. It is caused by the bacteria *M. pneumoniae.*
myelinated axon A nerve fiber having a myelin sheath.
myeloblast Bone marrow cell.
myocardial hypertrophy An abnormal increase in the size of cardiac muscle.
myocardial infarction Necrosis of a portion of cardiac muscle caused by obstruction in a coronary artery from atherosclerosis or an embolus.
myoclonic seizure A seizure that causes brief muscle contractions that usually occur at the same time and on both sides of the body.
myoclonus A condition characterized by rapid, uncontrollable muscular contractions or spasms of muscles that occur at rest or during movement.
myoepithelium Tissue made up of contractile epithelial cells.
myofibril A slender, striated strand of smooth muscle.
myofilament An extremely fine, molecular, threadlike structure that helps to form the myofibril of muscle; thick myofibrils are formed of myosin, and thin myofilaments are formed of actin.
myoglobinuria The presence of myoglobin in the urine.
myometrium The muscular wall of the uterus.
myosin A cardiac and skeletal muscle protein; it makes up about half of the proteins that occur in muscle tissue.
myositis A muscular disorder characterized by progressive muscle weakness and wasting; also known as *inclusive body myositis*.
myxedema A condition that results from a deficiency in thyroid hormone.
nail bed The end of a finger or toe covered by the nail; it is abundant in blood vessels.
nail body The visible part of the nail.
narcolepsy A syndrome characterized by sudden sleep attacks and visual or auditory hallucinations at the onset of sleep.
nares Nostrils.
narrative The portion of the patient care report that allows for a chronological description of the call.
nasal bone The bony partition that separates the nasal cavity into left and right parts; also known as the *nasal septum.*
nasal septum A partition that separates the right and left nasal cavities.
nasogastric decompression The management of gastric distention or emesis control by means of a nasogastric tube.
nasogastric tube Any tube passed into the stomach through the nose.
nasolacrimal duct A duct that leads from the lacrimal sac to the nasal cavity.
nasopharynx The uppermost portion of the pharynx just behind the nasal cavities.
nasotracheal Accessing the trachea through the nasal cavity.
natural immunity Non–antigen-specific immunity that is present at birth; also known as *innate immunity* or *nonspecific immunity.*
nature of the illness The principal characteristics and causes of an illness.
near-drowning Submersion with at least temporary survival.
near-fatal asthma Acute asthma associated with respiratory arrest, a drop in blood pressure, and reduced cardiac output.
nebulizer A device for producing a fine spray of medication for inhalation therapy.
necrosis Death of a cell or group of cells as the result of disease or injury.
necrotizing fasciitis A rare infection of the deep layers of the skin and subcutaneous tissues.
negative feedback mechanisms Any mechanism that tends to produce a response that balances a change in a system.
neglect The refusal or failure of the caregiver to fulfill obligations or duties to a person.
negligence Failure to use such care as a reasonably prudent emergency medical services provider would use in similar circumstances.
nematocyst A capsule containing threadlike, venomous stinging cells found in some coelenterates.
neonate An infant in the first 28 days of life.
neoplasia The new and abnormal development of cells, which may be benign or malignant.
neoplasm Abnormal growth; a malignant or benign tumor.
nephron The functional unit of the kidney.
nerve A bundle of nerve fibers and accompanying connective tissue located outside the central nervous system.
nerve tract Bundles of parallel axons with associated sheaths in the central nervous system.
nervous tissue A major tissue type characterized by its conductive abilities.
nervous tunic The retina.
neuralgia Pain along a nerve.
neurogenic hypotension Hypotension following spinal shock; caused by a loss of sympathetic tone to the vessels.
neurogenic shock Shock resulting from vasomotor paralysis below the level of injury; also known as *spinal cord shock.*

neuroglia Specialized connective tissue cells that protect and hold functioning neurons together.
neurohormone A junction hormone secreted by a neuron.
neuromuscular A specialized synapse between a motor neuron and a muscle fiber.
neuromuscular junction The area of contact between the ends of a large myelinated nerve fiber and a fiber of skeletal muscle.
neuron The functional unit of the nervous system, consisting of the nerve cell body, the dendrites, and the axon.
neuropathy A disease of the peripheral nerves.
neurosis Any faulty or inefficient way of coping with anxiety or inner conflict; it may ultimately lead to a neurotic disorder.
neurotransmitter A chemical that is released from one neuron at the presynaptic nerve fiber.
neutrophil A small, phagocytic white blood cell with a lobed nucleus and small granules in the cytoplasm.
newborn An infant in the first few hours of life.
Newton's first law of motion The principle that an object, whether at rest or in linear motion, remains in that state unless force is applied.
Newton's second law of motion The principle that force is equal to mass times acceleration or deceleration.
nicad batteries Nickel cadmium rechargeable batteries, which are used in portable radios.
nicotinic receptor A class of cholinergic receptor molecules that are activated specifically by nicotine and acetylcholine.
nit The egg of a parasitic insect, particularly a louse.
nitrogen narcosis An illness associated with scuba diving in which nitrogen becomes dissolved in solution as a result of greater than normal atmospheric pressure; also known as rapture of the deep.
nocturia Particularly excessive urination at night.
node of Ranvier The short interval in the myelin sheath of a nerve fiber between adjacent Schwann cells.
noncardiogenic pulmonary edema See *acute respiratory distress syndrome*.
noncompensatory pause The pause that occurs when the next expected P wave of the underlying cardiac rhythm appears earlier than it would have if the sinoatrial node had not been disturbed by a conduction abnormality.
noncompetitive antagonist An agent that combines with different parts of the receptor mechanism and inactivates the receptor so that the agonist cannot be effective regardless of its concentration.
nonconducted premature atrial complex A premature atrial complex blocked at the atrioventricular node.
nonelectrolyte A substance with no electrical charge.
nonepileptic seizure A seizure that stems from psychological causes rather than electrical disturbances in the brain.
Non-Hodgkin's lymphoma Cancer of the lymphoid tissue, which includes the lymph nodes, spleen, and other organs of the immune system.
nonproprietary name See *generic name*.
nonsteroid hormones Hormones that are synthesized chiefly from amino acids, including insulin, parathyroid hormone, and others.
Non-ST-elevation MI (NSTEMI) Myocardial infarction characterized by ischemic ST-segment depression equal to or greater than 0.5 mm (0.05 mV) or dynamic T-wave inversion with pain or discomfort. Nonpersistent or transient ST-segment elevation equal to or greater than 0.5 mm (0.05 mV) for more than 20 minutes is also included in this category.
nonstriated muscle See *smooth muscle*.
noradrenaline An adrenergic hormone produced by the adrenal medulla, similar in chemical and pharmacological properties to epinephrine. It acts to increase blood pressure by vasoconstriction but does not affect cardiac output; also known as norepinephrine.
nuchal rigidity Neck stiffness with flexion, suggesting meningeal irritation.
nuclear membrane A double membrane structure surrounding and enclosing the nucleus; also known as the *nuclear envelope*.
nucleic acids Extremely complex, long-chain compounds of high molecular weight that occur naturally in the cells of all living organisms; they form the genetic material of the cell and direct the synthesis of protein within the cell.
nucleolus Any one of the somewhat rounded, dense, well-defined nuclear bodies with no surrounding membrane; the nucleolus contains ribosomal RNA and protein.
nucleoplasm The protoplasm of the nucleus, as contrasted with that of the cell.
nucleus The central controlling body within a living cell.
nullipara A woman who has never borne a child.
nutrient Any substance that nourishes and aids the growth and development of the body.
nystagmus Involuntary rhythmic movements of the eyes.
obesity A condition in which a person is 30% above ideal body weight.
obligate Necessary; compulsory.
obsessive-compulsive disorder A psychiatric disorder in which the person feels stress or anxiety about thoughts or rituals over which he or she has little control.
obstructive apnea A form of sleep apnea involving a physical obstruction of the upper airways that can lead to pulmonary failure, chronic fatigue, and cardiac abnormalities.
obstructive shock Shock that results from obstruction to blood flow.
obtundation A state of being insensitive to unpleasant or painful stimulation associated with a reduced level of consciousness, such as by anesthesia or a strong narcotic analgesic.
obturator foramen A large opening on each side of the lower portion of the hipbone, formed posteriorly by the ischium, superiorly by the ilium, and anteriorly by the pubis.

occipital bone The cuplike bone at the back of the skull, marked by a large opening (the foramen magnum) that communicates with the vertebral canal.

occipital foramen A passage in the occipital bone through which the spinal cord enters the spinal column.

occipital lobe One of the five lobes of each cerebral hemisphere.

occiput posterior presentation An abnormal presentation in which the infant's head is delivered face up instead of face down.

occlusive stroke A stroke (CVA) caused by blockage of a cerebral blood vessel.

oculomotor nerve The third cranial nerve, which contains sensory and motor fibers; it provides for movement in most of the muscles of the eye, for constriction of the pupil, and for accommodation of the eye to light.

odontoid process The toothlike projection that rises perpendicularly from the upper surface of the body of the second cervical vertebra (also known as the *axis*), which serves as a pivot point for the rotation of the atlas.

official name The name of a drug that is followed by the initials USP (*United States Pharmacopeia*) or NF (*National Formulary*), denoting its listing in one of the official publications; usually the same as the generic name.

off-line (indirect) medical direction The establishment and monitoring of all medical components of an emergency medical services system, including protocols, standing orders, educational programs, and the quality and delivery of online (direct) medical direction.

olecranon fossa The depression in the posterior surface of the humerus that receives the olecranon of the ulna when the forearm is extended.

olecranon process The large bony process of the ulna; also known as the olecranon.

olfactory Of or pertaining to the sense of smell.

olfactory bulb The tissue that receives the olfactory nerves from the nasal cavity.

olfactory membranes Membranes that contain the receptors for the sense of smell; they are located in the roof of the nasal cavity.

olfactory recess The extreme superior region of the nasal cavity.

olfactory tract The nerve tract that projects from the olfactory bulb to the olfactory cortex.

oliguria A diminished capacity to form or pass urine.

omphalocele Congenital herniation of intraabdominal viscera through a defect in the abdominal wall around the umbilicus.

oncotic pressure See *blood colloid osmotic pressure*.

ongoing assessment A repeat of the initial assessment that is performed throughout the paramedic-patient encounter.

online (direct) medical direction The medical direction physician or designee who directly supervises prehospital care activities via radio or phone. Online (direct) medical direction may also be responsible for the activities of the emergency department staff and others at the medical direction hospital.

onset of action The interval between the time a drug is administered and the first sign of its effects; also known as the *latent period of drug action*.

oocyte An incompletely developed ovum.

open-angle glaucoma The most common type of glaucoma where structures of the eye appear normal, but fluid in the eye does not flow properly through the trabecular meshwork; also called *wide-angle glaucoma*.

open-ended questions Questions asked in a narrative form that cannot be answered with a "yes" or "no."

open pneumothorax A chest wall injury that exposes the pleural space to atmospheric pressure.

open vault fracture A fracture that results in direct communication between a scalp laceration and cerebral substance.

opening questions Questions that determine why the patient is seeking medical care or advice.

opiate A narcotic drug that contains opium, derivatives of opium, or any of several semisynthetic or synthetic drugs with opium-like activity.

opioid Any synthetic narcotic that has opiate-like activities but is not derived from opium.

opportunistic infections Infections that take advantage of weakness in the immune defenses.

opposition Movement of the thumb and little finger toward each other for the purpose of grasping objects.

optic nerve The nerve that carries visual signals from the eye to the crossing of the optic tracts.

oral candidiasis An infection of yeast fungi of the genus *Candida* on the mucous membranes of the mouth; also known as *thrush*.

orbital cellulitis An acute infection of the tissues immediately surrounding the eye, including the eyelids, eyebrow, and cheek.

orchitis Painful inflammation of the testicle.

organ A structure made up of two or more kinds of tissues organized to perform a more complex function than any one tissue alone.

organ of Corti The organ of hearing; it is located in the cochlea and filled with endolymph.

organelle Any one of various particles of living substance bound within most cells, such as the mitochondria, the Golgi apparatus, the endoplasmic reticulum, the lysosomes, and the centrioles.

oriented Aware of one's surroundings.

origin The less movable attachment point of a muscle.

orogastric decompression The management of gastric distention or emesis control by means of an orogastric tube.

oropharyngeolaryngeal axis The three axes of the mouth, pharynx, and trachea; a patient position used for direct visualization of the larynx.

oropharynx The portion of the pharynx located behind the mouth.

orotracheal Gaining access to the trachea through the oral cavity.
orphan drug A medication that has been developed specifically to treat a rare medical condition.
orthostatic hypotension Abnormally low blood pressure that occurs when an individual assumes the standing posture; also called postural hypotension.
osmolality The osmotic concentration of a solution.
osmosis Diffusion of solvent (water) through a membrane from a less concentrated solution to a more concentrated solution.
osmotic pressure The force required to prevent the movement of water across a selectively permeable membrane.
ossified To be changed or developed into bone.
osteoarthritis A form of arthritis in which one or many joints undergo degenerative changes.
osteomyelitis Local or generalized infection of bone and bone marrow, usually caused by bacteria introduced by trauma or surgery.
osteoporosis A disorder characterized by a reduction in bone density; it occurs most often in postmenopausal women.
ostomy An artificial opening into the urinary tract, gastrointestinal tract, or trachea; any surgical procedure in which an opening is created between two hollow organs or between a hollow viscus and the abdominal wall.
otitis media Infection or inflammation of the middle ear.
otorrhea Any discharge from the external ear.
ounce A unit of weight equal to $\frac{1}{16}$ lb, or 28.349 g.
ovarian follicle The spherical cell aggregation in the ovary that contains an oocyte.
ovarian ligament The bundle of fibers that passes to the uterus from the ovary.
ovarian torsion Twisting of an ovary around its vascular pedicle.
ovary One of the pair of female gonads found on each side of the lower abdomen beside the uterus.
overflow incontinence An overflow of urine from the bladder.
overhydration Water excess or water intoxication.
ovulation The release of an ovum or secondary oocyte from the vesicular follicle.
oxyhemoglobin Oxygenated hemoglobin.
P wave The first complex of the electrocardiogram, representing depolarization of the atria.
pacemaker cell Certain myocardial cells capable of initiating an electrical impulse.
packaging See *patient packaging*.
Paget's disease A common, nonmetabolic disease of bone of unknown cause characterized by excessive bone destruction and unorganized bone repair.
paging equipment Equipment typically using tone activation with one-way transmission to receive-only units.
palate A structure that forms the roof of the mouth; it is divided into the hard and soft palates.
palatine bone One of a pair of bones of the skull forming the posterior part of the hard palate, part of the nasal cavity, and the floor of the orbit of the eye.
palatine tonsil One of two large oval masses of lymphoid tissue embedded in the lateral wall of the oropharynx.
palliative care A unique form of health care primarily directed at providing relief to terminally ill persons through symptom management and pain management; also known as *comfort care*.
palmar grasp A normal infant response. The infant curls the fingers in response to a touch on the palm of the hand.
palpation A technique in which an examiner uses the hands and fingers to gather information from a patient by touch.
pancreas A fish-shaped nodular gland located across the posterior abdominal wall in the epigastric region of the body; it secretes various substances, including digestive enzymes, insulin, and glucagon.
pancreatic juice The fluid secretion of the pancreas produced by the stimulation of food in the duodenum.
pancreatitis Inflammation of the pancreas, which causes severe epigastric pain.
pandemic An infectious disease outbreak that infects large numbers of people in a large geographic region and may occur worldwide.
panic disorder An anxiety disorder characterized by unexpected and repeated episodes of intense fear accompanied by physical symptoms that may include chest pain, heart palpitations, shortness of breath, dizziness, or abdominal distress.
papilledema Swelling of the head of the optic disc, caused by a rise in intracranial pressure (ICP).
para The number of past pregnancies that have remained viable to delivery.
parainfluenza virus One of a group of viruses isolated from patients with upper respiratory tract disease of varying severity in infants and young children; it may cause croup, tracheobronchitis, bronchiolitis, bronchopneumonia, pharyngitis, and the common cold.
paralytic ileus The decrease in or absence of intestinal peristalsis that may occur after abdominal surgery, illness, or injury; the most common cause of intestinal obstruction.
paramedic a person who has completed training consistent with the national EMS education standards, including advanced training in clinical decision making, patient assessment, cardiac rhythm interpretation, defibrillation, drug therapy, and airway management.
parametritis An inflammatory condition of tissue of the structures around the uterus.
paranoia A condition characterized by an elaborate, overly suspicious system of thinking.
paraphimosis The inability of an uncircumcised male to pull the retracted foreskin back over the head of the penis.
paraplegia A weakness or paralysis of both legs and sometimes part of the trunk.

parasagittal plane An imaginary vertical plane passing through the body parallel to the medial plane; it divides the body into left and right portions.

parasympathetic Of or pertaining to the craniosacral division of the autonomic nervous system.

parasympathetic nervous system The subdivision of the autonomic nervous system usually involved in activating vegetative functions such as digestion, defecation, and urination.

parasympatholytic agent Anticholinergic; producing effects resembling those of interruption or blockade of the parasympathetic nerve supply to effector organs or tissues.

parasympathomimetic agent An agent with effects that mimic those resulting from stimulation of parasympathetic nerves, especially the effects produced by acetylcholine.

parasystole An independent ectopic rhythm initiated at a site other than the normal pacemaker of the heart (i.e., the sinoatrial node); the ectopic focus cannot be activated by impulses of the dominant rhythm because it is surrounded by an area of depressed conduction.

parenchyma The essential or functional elements of an organ.

parens patriae A term that refers to the authority of the state to intervene over the objections of parents to protect children.

parenteral Of or pertaining to any medication route other than the alimentary canal.

paresthesia A sensation of numbness, tingling, or "pins and needles."

parietal Of or pertaining to the outer wall of a cavity or organ.

parietal bone One of a pair of bones that form the side of the cranium.

parietal lobe The portion of each cerebral hemisphere that occupies the parts of the lateral and medial surfaces covered by the parietal bone.

parietal pericardium The portion of serous pericardium lining the fibrous pericardium.

parietal peritoneum The layer of peritoneum lining the abdominal walls.

Parkinson's disease A disease caused by degeneration or damage (of unknown origin) to nerve cells within the basal ganglia in the brain.

parkinsonism A neurological disorder characterized by tremor, muscle rigidity, hypokinesia, a slow shuffling gait, and difficulty in chewing, swallowing, and speaking; it frequently occurs in patients treated with antipsychotic drugs.

paronychia A common skin infection that occurs around the nails that that allows for an invasion of bacteria, yeast, or fungus.

parotitis Inflammation or infection of one or both parotid salivary glands.

paroxysm A sudden attack or recurrence of symptoms of a disease.

paroxysmal nocturnal dyspnea An abnormal condition of the respiratory system characterized by sudden attacks of shortness of breath, profuse sweating, tachycardia, and wheezing that awaken a person from sleep; often associated with left ventricular failure and pulmonary edema.

paroxysmal supraventricular tachycardia An ectopic rhythm in excess of 100 beats per minute and usually faster than 170 beats per minute that begins abruptly with a premature atrial or junctional beat and is supported by an atrioventricular nodal reentry mechanism or by an atrioventricular reentry involving an accessory pathway.

partial antagonist An agent that has affinity and some efficacy but that may antagonize the action of other drugs that have greater efficacy.

partial pressure The pressure exerted by a single gas.

partial reabsorption The amount of drug reabsorbed from the renal tubule by passive diffusion.

partial seizure A seizure that originates from an identifiable cortical lesion.

partial-thickness burn A burn injury that extends through the epidermis to the dermis; considered a deep partial-thickness injury if it extends to the basal layers of the skin; also known as a *second-degree burn.*

parturition The process of giving birth.

passive glomerular filtration The renal process whereby fluid in the blood is filtered across the capillaries of the glomerulus and into the urinary space of Bowman's capsule.

passive immunity Immunity acquired by the transfer of antibodies from the mother by way placental transfer to the fetus; a form of acquired immunity in which antibodies against disease are acquired naturally.

past medical history A patient's medical background that may offer insight into the patient's current problem.

patella A flat, triangular bone at the front of the knee joint; the kneecap.

pathogen A disease-causing agent.

pathogenic microbes Microscopic pathogens such as bacteria, parasites, fungi, and viruses that can cause infection.

pathological fracture A bone fracture that results from trauma or a metabolic disease, such as osteoporosis or a bone tumor.

patient care report A document used in the prehospital setting to record all patient care activities and circumstances related to an emergency response.

patient management plan A plan of care that is based on principles and applications of findings in the patient assessment.

patient packaging Completion of emergency care procedures needed to transfer a patient from the scene to the emergency vehicle.

pattern recognition The process of comparing gathered information with the paramedic's knowledge base of medical illness and disease.

patterned injuries Injuries that result from an identifiable object.
peak expiratory flow rate A measurement of how fast a person can exhale air.
peak plasma level The highest plasma concentration attained from a dose.
pectoral girdle See *shoulder girdle*.
pectus deformity Malformation of the chest wall.
pediatric trauma score An injury severity index that grades six components commonly seen in pediatric trauma patients: size (weight), airway, central nervous system, systolic blood pressure, open wound, and skeletal injury.
pelvic cavity The area of the body enclosed by the bones of the pelvis.
pelvic girdle The encircling bony structure supporting the lower limbs.
pelvic inflammatory disease Any inflammatory condition of the female pelvic organs, especially one caused by bacterial infection.
penetrating trauma An injury produced by crushing and stretching forces of a penetrating object that results in some form of tissue disruption.
penetration The flow of a hazardous liquid chemical through zippers, stitched seams, pinholes, or other imperfections in a material.
penis The external reproductive organ of the male.
pepsin The principal digestive enzyme of gastric juice.
pepsinogen A proenzyme formed and secreted by certain cells of the gastric mucosa.
peptic ulcer A sharply circumscribed loss of the mucous membrane of the stomach, duodenum, or any other part of the gastrointestinal system.
peptic ulcer disease Illness that results from a complex pathological interaction among the acidic gastric juice and proteolytic enzymes and the mucosal barrier.
peptide bond A chemical bond between amino acids.
percussion A technique used to evaluate the presence of air or fluid in body tissues.
perforated tympanic membrane A hole or rupture in the eardrum, usually from trauma or infection.
perfusion The circulation of blood to the tissues.
periappendiceal abscess A cavity containing pus and inflamed tissue around the vermiform appendix.
pericardial cavity The area of the body that surrounds the heart.
pericardial fluid A viscous fluid contained within the pericardial cavity between the visceral and parietal pericardium; it serves as a lubricant.
pericardial friction rub A dry, grating sound heard with a stethoscope during auscultation; suggestive of pericarditis.
pericardial sac The sac that surrounds the heart.
pericardial tamponade Compression of the heart produced by the accumulation of fluid or blood in the pericardial sac.
pericardiocentesis A procedure for withdrawing fluid from the pericardial sac.
pericarditis Inflammation of the pericardium.
pericardium The membrane that surrounds the heart.
perilymph The fluid contained within the bony labyrinth.
perinatal Occurring at or near the time of birth.
perineum The pelvic floor and associated structures occupying the pelvic outlet, bounded anteriorly by the pubic symphysis, laterally by the ischial tuberosities, and posteriorly by the coccyx.
periodontal disease Disease that affects tissue that surround or support the teeth.
periodontal membrane The membrane that surrounds the root of the tooth.
periosteum Tough connective tissue that covers the bone.
periostitis Inflammation of the periosteum characterized by tenderness and swelling of the affected bone, pain, fever, and chills.
peripheral nervous system A subdivision of the nervous system consisting of nerves and ganglia.
peripheral neuropathy Diseases and disorders that affect the peripheral nervous system, including spinal nerve roots, cranial nerves, and peripheral nerves.
peripheral thermoreceptors Nerve endings sensitive to heat, located in the skin and some mucous membranes; they usually are categorized as cold or warm receptors.
peripheral vascular disease Any abnormal condition that affects the blood vessels outside the heart and lymphatic vessels.
peripheral vascular resistance The total resistance against which blood must be pumped; also known as *afterload*.
peristalsis The coordinated, rhythmic, and serial contraction of smooth muscle that forces food through the digestive tract, bile through the bile duct, and urine through the ureters.
peristaltic Pertaining to peristalsis.
peritoneal Pertaining to the peritoneum.
peritoneal cavity The potential space between the parietal and visceral layers of the peritoneum; the two layers normally are in contact.
peritoneal dialysis A dialysis procedure that uses the peritoneum as a diffusible membrane; performed to correct an imbalance of fluid or electrolytes in the blood or to remove toxins, drugs, or other wastes normally excreted by the kidney.
peritoneum The serous membrane that covers the abdominal wall of the body and is reflected over the contained viscera.
peritonitis Inflammation of the serous membrane that covers the abdominal wall.
peritonsillar abscess A collection of pus in and around one or both tonsils; often caused by tonsillitis.
peritubular capillary The capillary network located in the cortex of the kidney.

permeable A condition of being pervious so that fluids and other substances can pass through, as occurs in a semipermeable membrane.

permeation The process by which a hazardous liquid chemical moves through a material on a molecular level.

permissive hypotension A fluid resuscitation strategy that advocates withholding fluid and red cell products until after surgical control of bleeding is achieved.

pernicious anemia Anemia that results from a vitamin B_{12} deficiency.

PERRL Acronym for pupils that are equal, round, and react to light.

persistent generalized lymphadenopathy Enlarged lymph nodes involving two noncontiguous sites other than the inguinal nodes; a common feature in early human immunodeficiency virus infection.

personal protective equipment Clothing or specialized equipment that provides some protection to the wearer.

personality disorder A large group of conditions distinguished by a failure to learn from experience or to adapt appropriately to changes; results in personal distress and impairment of social functioning.

pertinent negative findings Findings that warrant no medical care or intervention but that, by seeking them, show evidence of the thoroughness of the examination and history of the event.

pertussis An acute, highly contagious respiratory disease characterized by paroxysmal coughing that ends in a loud, whooping inspiration; also known as *whooping cough*.

petit mal seizure An epileptic seizure characterized by a sudden, momentary loss of consciousness occasionally accompanied by minor muscle spasms of the neck or upper extremities.

pH An inverse logarithm of the hydrogen ion concentration.

phagocytic Pertaining to phagocytosis.

phagocytosis The process of ingestion by cells of solid substances such as other cells, bacteria, bits of necrosed tissue, and foreign particles.

phalanges Any bone of a finger or toe.

pharmaceutics The science of dispensing drugs.

pharmacodynamics The study of how a drug acts on a living organism.

pharmacokinetics The study of how the body handles a drug over a period of time, including the processes of absorption, distribution, biotransformation, and excretion.

pharmacology The science of drugs used to prevent, diagnose, and treat disease.

pharyngeal tonsil One of two collections of aggregated lymphoid nodules on the posterior wall of the nasopharynx.

pharyngitis Inflammation or infection of the pharynx.

phase 0 The rapid depolarization phase; it represents the rapid upstroke of the action potential that occurs when the cell membrane reaches the threshold potential (approximately −70 mV).

phase 1 The early rapid repolarization phase; the phase in which the fast sodium channels close, the flow of sodium ions into the cell terminates, and the loss of potassium from the cell continues.

phase 2 The plateau phase; the prolonged phase of slow repolarization of the action potential.

phase 3 The terminal phase of rapid repolarization; it results in the inside of the cell becoming considerably negative and the membrane potential returning to approximately −90 mV, or its resting level.

phase 4 The period between action potentials when the membrane has returned to its resting membrane potential.

phencyclidine psychosis A true psychiatric emergency with clinical syndromes ranging from a catatonic and unresponsive state to bizarre and violent behavior; it may occur after a single low-dose exposure to phencyclidine and may last several days to weeks.

phimosis Tightness of the prepuce (foreskin) of the penis of an uncircumcised male.

phlebitis Inflammation of a vein, often accompanied by formation of a clot; also known as *thrombophlebitis*.

phlebotomy The incision or puncture of a vein for allowing the collection of blood.

phobia An anxiety disorder characterized by an obsessive, irrational, and intense fear of a specific object or activity.

phonation The production of speech sounds.

phosgene A poisonous gas that appears as a grayish white cloud and smells of newly mowed hay.

phospholipid One of a class of compounds, widely distributed in living cells, that contains phosphoric acid, fatty acids, and a nitrogenous base.

photophobia Abnormal sensitivity to light.

phrenic nerve A nerve comprised mostly of motor nerve fibers that produce contractions of the diaphragm; also provides sensory innervation for many components of the mediastinum and pleura.

physical abuse The use of physical force that may result in bodily injury, physical pain, or impairment.

physical dependence An adaptive physiological state that occurs after prolonged use of many drugs; discontinuation causes withdrawal syndromes that are relieved by readministering the same drug or a pharmacologically related drug.

physical examination An assessment of a patient that includes examination techniques, measurement of vital signs, an assessment of height and weight, and the skillful use of examination equipment.

physiological dead space The sum of the anatomical dead space plus the volume of any nonfunctional alveoli.

pia mater The innermost layer of the meninges that directly covers the brain.

Pick's disease A rare neurodegenerative disease associated with the shrinking of the frontal and temporal anterior lobes of the brain.

pickwickian syndrome An abnormal condition characterized by obesity, decreased pulmonary function, somnolence, and polycythemia.

pigmented retina The pigmented portion of the retina.

piloerection Erection of the hairs of the skin in response to cold environment, emotional stimulus, or irritation of the skin.

pineal gland A cone-shaped structure in the brain that secretes the hormone melatonin.

pinna See *auricle*.

piriformis syndrome A neuromuscular disorder associated with irritation or compression of the sciatic nerve.

pitting edema Observable indentation of body tissues that persists after applying pressure to an area swollen from fluid accumulation.

pituitary gland A small gland attached to the hypothalamus; it supplies numerous hormones that govern many vital processes.

pivot joint A joint that consists of a relatively cylindrical bony process that rotates within a ring composed partly of bone and partly of ligament.

placards Four-sided, diamond-shaped signs displayed on hazardous materials containers that usually are yellow, orange, white, or green. They have a four-digit United Nations identification number and a legend to indicate the contents of the container.

placebo An inactive substance or a less than effective dose of a harmless substance; it is used in experimental drug studies to compare the effects of the inactive substance with those of the experimental drug.

placenta A highly vascular fetal-maternal organ through which the fetus absorbs oxygen, nutrients, and other substances and excretes carbon dioxide and other wastes.

placenta previa A condition of pregnancy in which the placenta is implanted abnormally in the uterus so that it impinges on or covers the internal os of the uterine cervix.

placental barrier A protective biological membrane that separates the blood vessels of the mother and the fetus.

plague A disease caused by the bacteria *Yersinia pestis,* found in rodents (e.g., chipmunks, prairie dogs, ground squirrels, and mice) and their fleas in many areas around the world.

plane joint A joint that consists of two opposed flat surfaces that are approximately equal in size; also known as a *gliding joint.*

plasma The fluid portion of blood.

plasma membrane The outer covering of a cell that contains the cellular cytoplasm; also known as the cell membrane.

plasma-protein binding A type of drug reservoir in which drugs attach to proteins, mainly albumin, and form a drug-protein complex.

plateau phase Prolongation of the depolarization phase of the cardiac muscle cell membrane; it results in a prolonged refractory period.

platelet A fragment of a cell; it contains granules in the central part and clear protoplasm peripherally but has no definite nucleus.

platelet plug A plug consisting of a mass of linked platelets that seals an injured vessel; part of the clotting cascade.

pleural cavity The area of the body that surrounds the lungs.

pleural fluid Serous fluid found in the pleural cavity; it helps to reduce friction when the pleural membranes rub together.

pleural friction rub A rubbing or grating sound that occurs as one layer of the pleural membrane slides over the other during breathing.

pleural lavage A rewarming technique that uses warm saline to irrigate the thorax; it is used to treat some patients with severe hypothermia.

pleural space The potential space between the visceral and parietal layers of the pleura.

pleurisy Inflammation of the parietal pleura of the lungs, characterized by dyspnea and stabbing chest pain.

plexus A network of intersecting nerves and blood vessels or lymphatic vessels.

pneumatic antishock garment A garment used to manage some forms of hypovolemia and to stabilize some fractures.

pneumococcus A gram-positive diplococcal bacterium of the species *Diplococcus pneumoniae;* the most common cause of bacterial pneumonia.

***Pneumocystis carinii* pneumonia** A bacterial pneumonia caused by infection with the parasite *Pneumocystis carinii;* it usually is seen in infants or debilitated or immunosuppressed persons and is characterized by fever, cough, tachypnea, and, frequently, cyanosis.

pneumohemothorax A collection of air and blood in the pleural space; also known as a *hemopneumothorax.*

pneumomediastinum The presence of air or gas in the mediastinal tissues.

pneumonia An acute inflammation of the lungs, usually caused by inhaled pneumococci of the species *Streptococcus pneumoniae.*

pneumopericardium The presence of air or gas in the pericardial cavity.

pneumoperitoneum The presence of air or gas within the peritoneal cavity of the abdomen.

pneumotaxic center A group of neurons in the pons that have an inhibitory effect on the inspiratory center.

pneumothorax A collection of air or gas in the pleural space that causes the lung to collapse.

poikilothermy Variation in body temperature according to the ambient temperature.

point of maximum impulse The location or area where the apical pulse is palpated the strongest, often in the fifth intercostal space of the thorax just medial to the left midclavicular line.

point-to-point movements Refers to methods used to evaluate a patient's coordination.

poison Any substance that produces harmful physiological or psychological effects.
polio See *poliomyelitis*.
poliomyelitis An infectious disease caused by one of three polio viruses; asymptomatic, mild, and paralytic forms of the disease occur.
poliovirus hominis The causative organism of poliomyelitis.
polyarthritis Inflammation of several joints.
polycythemia A condition characterized by an unusually large number of red cells in the blood as a result of their increased production by the bone marrow.
polydipsia Excessive thirst.
polymorphic Occurring in many forms.
polymyositis Slow, but progressive muscle weakness that affects skeletal muscle on both sides of the body.
polyp A small, tumorlike growth that projects from a mucous membrane surface.
polyphagia Excessive eating.
polysaccharide A carbohydrate that contains three or more molecules of simple carbohydrates.
polyuria Excessive secretion of urine.
pons The part of the brainstem between the medulla and the midbrain.
portal hypertension An increased venous pressure in the portal circulation caused by compression or by occlusion in the portal or hepatic vascular system.
portal of entry The means by which a pathogenic agent enters a new host.
portal of exit The method by which a pathogenic agent leaves one host to invade another.
portal vein A vein that ramifies like an artery in the liver and ends in capillary-like sinusoids that convey the blood to the inferior vena cava through the hepatic veins.
positive end-expiratory pressure Airway support that maintains a degree of positive pressure at the end of exhalation.
postcapillary sphincter The smooth muscle sphincter at the venous end of a capillary that regulates blood flow through the capillary.
posterior The back, or dorsal, surface.
posterior cerebral artery The artery that supplies the posterior portion of the cerebrum.
posterior chamber of the eye The chamber of the eye between the iris and the lens.
posterior communicating artery The artery that branches off each internal carotid artery and connects with the ipsilateral posterior cerebral artery.
posterior superior iliac spine One of two bony segments that form the iliac crest.
postictal phase The phase that usually follows a seizure in which the person is drowsy and lethargic.
postpartum The maternal period after delivery.
postpartum hemorrhage Blood loss of more than 500 mL after delivery of the newborn.
postrenal disease Refers to diseases that block the system that collects urine; usually caused by urinary tract obstruction.
postsynaptic neuron The membrane of a nerve that is in close association with a presynaptic terminal.
posttraumatic syndrome An anxiety reaction to a severe psychosocial event; also known as posttraumatic stress disorder.
postural maintenance The result of muscle tone responsible for keeping the back and legs straight, the head in an upright position, and the abdomen from bulging; also balances the distribution of body weight.
potassium ion The predominant intracellular cation; it helps to regulate neuromuscular excitability and muscle contraction.
potassium-sparing agent A group of medications that promote sodium and water loss without an accompanying loss of potassium.
potential difference The difference in electrical potential, measured as the charge difference across the cell membrane.
potentiation Enhancement of the effect of a drug, caused by concurrent administration of two drugs in which one drug increases the effect of the other.
pound A unit of measure equal to 16 oz, or 0.45359 kg.
P-R interval The time elapsing between the beginning of the P wave and the beginning of the QRS complex in the electrocardiogram.
precapillary sphincter The smooth muscle sphincter at the arterial end of a capillary that regulates blood flow through the capillary.
precipitous delivery A rapid, spontaneous delivery of less than 3 hours from onset of labor to birth; it results from overactive uterine contractions and little maternal soft tissue or bony resistance. Childbirth that occurs with such speed that usual preparations cannot be made.
precordial thump A cardiopulmonary resuscitation technique used to restore circulation in monitored ventricular fibrillation or unstable ventricular tachycardia.
preeclampsia An abnormal disease of pregnancy characterized by the onset of acute hypertension after 24 weeks' gestation.
pregravid Before pregnancy.
preload The amount of blood returning to the ventricle.
premature atrial complex A cardiac dysrhythmia characterized by an atrial beat occurring before the expected excitation and indicated on the electrocardiogram as an early P wave.
premature birth Refers to an infant who is born before 37 weeks' gestation.
premature junctional complex A cardiac dysrhythmia that occurs during sinus rhythm earlier than the next expected sinus beat and is caused by premature discharge of an ectopic focus in the atrioventricular junctional tissue.

premature rupture of membranes Rupture of the amniotic sac before the onset of labor, regardless of gestational age.

premature ventricular complex A cardiac dysrhythmia characterized by a ventricular beat preceding the expected electrical impulse and indicated on the electrocardiogram as an early, wide QRS complex without a preceding related P wave.

prenatal Existing or occurring before birth.

prepuce In males, the free fold of skin that covers the glans penis; the foreskin. In females, the external fold of the labia minora that covers the clitoris.

prerenal disease Refers to diseases that compromise renal perfusion.

preschooler A child 3 to 5 years of age.

present illness Identification of the chief complaint and a full, clear, chronological account of the symptoms.

presenting part The part of the fetus that lies closest to the internal os of the cervix.

presenting the patient The effective communication and transfer of patient information in the course of out-of-hospital and hospital care.

pressure gradient The force produced by differences between atmospheric pressure, intrapulmonic pressure, and intrathoracic pressure.

pressure ulcers Sores or ulcers in the skin over a bony prominence that occur most frequently on the sacrum, elbows, heels, outer ankles, inner knees, hips, and shoulder blades of high-risk patients, especially those who are obese, elderly, or suffering from chronic diseases, infections, injuries, or a poor nutritional state.

presynaptic neuron The nerve terminal that contains neurotransmitter vesicles.

presynaptic terminal The enlarged axon terminal.

preterm infant An infant born before 37 weeks' gestation.

priapism Painful, persistent erection of the penis.

primary bronchus One of the two tubes arising at the inferior end of the trachea; each primary bronchus extends into one of the lungs.

primary contamination Exposure to a hazardous substance that is harmful only to the person exposed and that poses little risk of exposure to others.

primary epilepsy Epilepsy for which the cause is unknown; also known as *idiopathic epilepsy.*

primary follicle The ovarian follicle that contains the primary oocyte.

primary injury prevention The practice of preventing the occurrence of an injury.

primary oocyte The oocyte before the first meiotic division.

primary polycythemia A rare disorder of the bone marrow where an increased production of RBCs causes the blood to thicken; also known as *polycythemia vera.*

primary pulmonary hypertension Abnormally high pressure within the pulmonary circulation.

primary survey A component of the patient assessment to recognize and manage all immediate life-threatening conditions.

primary tumor A malignant tumor in the original site where it first arose.

prime mover A muscle that plays a major role in accomplishing movement.

primigravida A woman who is pregnant for the first time.

primipara A woman who has given birth only one time.

Prinzmetal's angina An atypical form of angina that occurs at rest rather than with effort; it is associated with gross ST segment elevation in the electrocardiogram that disappears when the pain subsides.

priority patients Patients who need immediate care and transport.

private space A comfortable distance from the patient's body; usually about 4 to 5 feet or twice the patient's arm length away (also known as *personal space*).

proarrhythmia A new or worsened rhythm disturbance seemingly generated by antidysrhythmic therapy.

prodromal stage The early period of labor before uterine contractions become forceful and frequent enough to result in progressive dilation of the uterine cervix.

progesterone A steroid sex hormone prescribed to treat various menstrual disorders, functional uterine bleeding, and repeated spontaneous abortions.

progestin Any group of hormones secreted by the corpus luteum, placenta, or adrenal cortex that have a progesterone-like effect on the uterus.

prokaryote A cell without a true nucleus and with nuclear material scattered throughout the cytoplasm.

prolapsed umbilical cord An umbilical cord that protrudes beside or ahead of the presenting part of the fetus.

proliferative phase The time between the end of menses and ovulation characterized by rapid division of endometrial cells and the development of follicles in the ovary.

pronation Rotation of the forearm so that the anterior surface is down.

pronator drift test A test to evaluate balance and upper extremity weakness; performed by having the patient close the eyes and hold both arms out from the body.

prone The position in which the patient is lying on the stomach (face down).

proprietary name See *trade name.*

proprioception Information about the position of the body and its various parts.

prostaglandin A class of naturally occurring fatty acids that affect body functions such as vasodilation, stimulation and contraction of uterine smooth muscle, and promotion of inflammation and pain.

prostate gland The gland that lies just below the male bladder; it secretes one of the components of semen.

prostatic hypertrophy Hypertrophy or enlargement of the prostate gland.

prostatitis Acute or chronic inflammation of the prostate gland.

prosthesis An artificial replacement for a missing part of the body, such as an artificial limb.

protein Any of a large group of naturally occurring, complex, organic nitrogen compounds.

prothrombin A chemical that is part of the clotting cascade; the precursor of thrombin.

prothrombin activator A substance that combines with an enzyme to increase its catalytic activity; converts prothrombin to thrombin.

protoplasm The living substance of a cell.

protraction Movement in the anterior direction.

pseudoaneurysm A condition resembling an aneurysm, caused by enlargement and tortuosity of a vessel.

pseudogout Inflammation caused by calcium pyrophosphate (CPP) crystals; often clinically indistinguishable from gout.

pseudomembranous colitis A life-threatening form of diarrhea caused by *Clostridium difficile.*

psoas muscle A long muscle originating from the transverse processes of the lumbar vertebrae and the fibrocartilage and sides of the vertebral bodies of the lower thoracic vertebrae and the lumbar vertebrae.

psoriasis A common, chronic, inheritable skin disorder characterized by circumscribed red patches covered by thick, dry, adherent scales that result from excessive development of epithelial cells.

psychological dependence Emotional reliance on a drug; manifestations range from a mild desire for a drug to craving and drug-seeking behavior to repeated compulsive use of a drug for its subjectively satisfying or pleasurable effects.

psychology The science or study of behavior.

psychomotor seizure A seizure manifested by impaired consciousness of variable degree; the patient carries out a series of coordinated acts that are inappropriate, bizarre, and serve no useful purpose, about which the patient is amnesic.

psychosis Maladaptive behavior involving major distortions of reality.

puberty The period of life when the ability to reproduce begins.

pubic lice Tiny parasites that concentrate in the pubic area.

pubis One of a pair of pubic bones that, with the ischium and the ilium, form the hipbone and join the pubic bone from the opposite side at the pubic symphysis.

public duty doctrine or rule The provision that a public official is generally not liable to individuals for his or her negligence in discharging public duties.

public service answering point A communications center that coordinates the deployment of emergency personnel and other resources required for an emergence response.

pulmonary artery The artery that carries deoxygenated blood from the right ventricle into the lung.

pulmonary capacity The sum of two or more pulmonary volumes.

pulmonary contusion Bruising of the lung tissue that results in rupture of the alveoli and interstitial edema.

pulmonary edema The accumulation of extravascular fluid in lung tissues and alveoli.

pulmonary embolism The blockage of a pulmonary artery by foreign matter such as fat, air, tumor tissue, or a thrombus that usually arises from a peripheral vein.

pulmonary hypertension A condition of abnormally high pressure within the pulmonary circulation.

pulmonary overpressurization syndrome A condition that results from expansion of trapped air in the lungs; it may lead to alveolar rupture and extravasation of air into extraalveolar locations.

pulmonary respiration The exchange of gases between the cells of the body and the outside environment.

pulmonary semilunar valve A valve that guards the orifice between the right ventricle and the pulmonary artery.

pulmonary surfactant Certain lipoproteins that reduce the surface tension of pulmonary fluids, allowing the exchange of gases in the alveoli of the lungs and contributing to the elasticity of pulmonary tissue.

pulmonary trunk The large elastic artery that carries blood from the right ventricle of the heart to the right and left pulmonary arteries.

pulmonary vein Any vein that carries oxygenated blood from the lung to the left atrium.

pulmonary ventilation The movement of air in and out of the lungs. This process brings oxygen into the lungs and removes carbon dioxide.

pulmonic pressure Pressure generated by the right side of the heart.

pulp The soft, spongy chamber of the tooth.

pulse deficit A condition that exists when the radial pulse is less than the ventricular rate; it indicates a lack of peripheral perfusion.

pulse pressure The difference between the systolic and diastolic blood pressures.

pulsus paradoxus An abnormal decrease in systolic blood pressure that drops more than 10 to 15 mm Hg during inspiration compared with expiration.

punctate Spotted; marked with points of puncture.

punctum The opening of each lacrimal canal.

puncture wound An open injury that results from contact with a penetrating object.

pupil The opening in the center of the iris that regulates the amount of light entering the eye.

purified protein derivative A dried form of tuberculin used in testing for past or present infection with tubercle bacilli.

Purkinje fibers Myocardial fibers that are a continuation of the bundle of His and that extend into the muscle walls of the ventricles.

pustule A small, circumscribed elevation of skin containing fluid, which is usually purulent.

pyelolithotomy Removal of a stone from a kidney by surgical incision.

pyelonephritis An inflammation of the kidney parenchyma associated with microbial infection.
pyloric sphincter A thickened, muscular ring in the stomach that separates the pylorus from the duodenum.
pyorrhea Discharge of pus.
pyrogen Any substance or agent that tends to cause a rise in body temperature.
pyrogenic A substance or agent that produces fever.
pyruvate The end product of glycolysis; it may be metabolized to lactate or acetyl coenzyme A.
QRS complex The principal deflection in the electrocardiogram, representing ventricular depolarization.
Q-T interval The time elapsing from the beginning of the QRS complex to the end of the T wave, representing the total duration of electrical activity of the ventricles.
quadriplegia A weakness or paralysis of all four extremities and the trunk.
R prime A subsequent positive deflection in the QRS complex that extends above the baseline and that is taller than the first R wave.
rabies An acute, usually fatal viral disease of the central nervous system of animals; it is transmitted from animals to human beings by infected blood, tissue, or, most commonly, saliva.
raccoon's eyes Ecchymosis of one or both orbits caused by fracture of the base of the sphenoid sinus.
radial tuberosity A large, oblong elevation at the distal end of the radius.
radioulnar syndesmosis The articulation of the radius and ulna, consisting of a proximal articulation, a distal articulation, and three sets of ligaments.
radius One of the bones of the forearm, lying parallel to the ulna.
range The general perimeter of communications coverage, beyond which coverage is nonexistent or severely degraded to an unusable level; it is measured in miles.
rape Nonconsensual sex, or an attempt to force another person to have sex against his or her will; includes intercourse in the vagina, anus, or mouth.
rapid sequence intubation An airway management technique that involves the virtually simultaneous administration of a potent sedative agent and a neuromuscular blocking agent for the purpose of endotracheal intubation; it provides optimal intubation conditions while minimizing the risk of aspiration of gastric contents.
rappelling A method of descent that involves lowering oneself with a rope.
Raynaud's phenomenon A condition in which cold temperatures or strong emotions cause blood vessel spasms that block blood flow to the fingers, toes, ears, and nose.
reabsorption The process of absorbing again that occurs in the kidneys.
reactive airway disease An inflammatory airway condition that develops as a reaction to an antigen.
reactive hyperemia Increased blood flow associated with increased metabolic activity.
reactivity The ability of a chemical to interact with other chemicals and body tissue.
reassessment The ongoing assessment that follows the paramedic's initial evaluation of the patient.
rebound tenderness A sign of peritoneal inflammation in which pain is caused by the sudden release of fingertip pressure on the abdomen.
receptor molecule A reactive site on the cell surface or within the cell that combines with a drug molecule to produce a biological effect.
reciprocal socialization A term that refers to a child's temperament and the responses it obtains from adults and family members. This interaction forms the basis for early social interactions with others and with the child's environment.
reciprocity The practice of granting an individual licensure or certification/registration based on licensure or certification/registration by another state, agency, or association.
rectal abscess An infected pus-filled cavity near the anus.
rectum The segment of the large intestine continuous with the descending sigmoid colon just proximal to the anal canal.
rectus femoris muscle A muscle of the anterior thigh; one of the four parts of the quadriceps femoris.
red marrow Specialized soft tissue found in many bones of infants and children, in the spongy bone of the proximal epiphyses of the humerus and femur, and in the sternum, ribs, and vertebral bodies of adults. It is essential in the manufacture of red blood cells.
red measles See *rubeola*.
reentry The reactivation of tissue by a returning impulse; the sustaining mechanism in some cases of ventricular bigeminy or trigeminy, ventricular tachycardia, and paroxysmal supraventricular tachycardia.
referred pain Visceral pain felt at a site distant from its origin.
reflection on action A component of critical thinking (usually performed after the event) in which the examiner evaluates a patient care episode for possible improvement in similar future responses.
reflex An automatic response to a stimulus that occurs without conscious thought; produced by a reflex arc.
reflex arc The smallest portion of the nervous system capable of receiving a stimulus and producing a response.
refractory period The period after effective stimulation during which excitable tissue fails to respond to a stimulus of threshold intensity.
refractory shock Shock that is resistant to treatment but is still reversible.
relative hypovolemia Inadequate preload as a result of vasodilation.
relative refractory period The portion of the action potential after the absolute refractory period during

which another action potential can be produced with a greater than threshold stimulus strength.

renal calculus Kidney stone.

renal calyx The first unit in the system of the ducts of the kidney carrying urine from the renal pyramid of the cortex to the renal pelvis for excretion through the ureters.

renal capsule The cortical substance that separates the renal pyramids.

renal corpuscle The glomerulus and its enclosing Bowman's capsule.

renal cortex The outer layer of the kidney, which contains approximately 1.25 million renal tubules, which remove body waste in the form of urine.

renal failure Inability of the kidneys to secrete wastes, concentrate urine, and conserve electrolytes; it may be chronic or acute.

renal medulla The inner layer of the kidney.

renal papilla The apex of the renal pyramid.

renal pelvis The funnel-shaped expansion of the upper end of the ureter that receives the calyces.

renal pyramid One of a number of pyramidal masses seen on longitudinal section of the kidney; it contains part of the loop of Henle and the collecting tubules.

renal tubule One of the collecting tubules in the kidney.

renin A proteolytic enzyme that surrounds each arteriole as it enters a glomerulus; it affects blood pressure by catalyzing the change of angiotensin I to angiotensin II.

renin-angiotensin-aldosterone mechanism Renin, released from the kidneys in response to low blood pressure, converts angiotensinogen to angiotensin I. Angiotensin I is converted by angiotensin-converting enzyme to angiotensin II, which causes vasoconstriction, resulting in increased blood pressure. Angiotensin II also increases aldosterone secretion, which increases blood pressure by increasing blood volume.

repolarization The phase of the action potential in which the membrane potential moves from its maximum degree of depolarization toward the value of the resting membrane potential.

reposition To move a structure to its original position.

reproductive maturity The time at which a person has attained the ability to reproduce.

rescue The act of delivery from danger or imprisonment.

reservoir Any person, animal, plant, soil, or substance in which an infectious agent normally lives and multiplies; typically harbors the infectious agent without injury to itself and serves as a source from which other individuals can be infected.

residual volume The volume of air remaining in the lungs after a maximum expiratory effort.

resistance The immune status of the host; the ability to ward off infection.

respiration The process of the molecular change of oxygen and carbon dioxide within the body's tissues.

respiratory acidosis An abnormal condition characterized by increased arterial P_{CO_2}, excess carbonic acid, and increased plasma hydrogen ion concentration.

respiratory alkalosis An abnormal condition characterized by decreased P_{CO_2}, decreased hydrogen ion concentration, and increased blood pH.

respiratory bronchiole The smallest bronchiole that connects the terminal bronchiole to the alveolar duct.

respiratory membrane The membrane in the lungs across which gas exchange occurs with the blood.

respiratory syncytial virus A single-strand virus that is a common cause of epidemics of acute bronchiolitis, bronchopneumonia, and the common cold in young children and sporadic acute bronchitis and mild upper respiratory tract infections in adults.

resting membrane potential The electrical charge difference inside a cell membrane measured relative to that just outside the cell membrane.

reticular activating system A functional system in the brain essential for wakefulness, attention, concentration, and introspection.

reticular Relating to a fine network of cells or collagen fibers.

reticular formation A small, thick cluster of neurons nestled within the brainstem that controls breathing, the heartbeat, blood pressure, level of consciousness, and other vital functions.

reticuloendothelial system Part of the immune system; it is composed of immune cells in the spleen, lymph nodes, liver, bone marrow, lungs, and intestines; stores mature B and T cells until the immune system is activated.

retina The nervous tunic of the eye; it is continuous with the optic nerve.

retinal detachment A separation of the light-sensitive retina from its supporting layers.

retinopathy A group of inflammatory eye disorders often caused by diabetes, hypertension, and atherosclerotic vascular disease.

retraction Movement in the posterior direction.

retrograde amnesia The loss of memory for events that occurred before the event that precipitated the amnesia.

retroperitoneal Of or pertaining to the organs closely attached to the abdominal wall and partly covered by peritoneum.

retroperitoneum Behind the peritoneum.

retrovirus Any of a family of viruses that converts genetic RNA to DNA after entering the host cell.

Revised Trauma Score An injury severity index that uses the Glasgow Coma Scale and measurements for systolic blood pressure and respiratory rate.

Reye's syndrome A combination of acute encephalopathy and fatty infiltration of the internal organs that may follow acute viral infections.

Rh factor An antigenic substance present in the erythrocytes of most persons; a person lacking the Rh factor is Rh negative.

rhabdomyolysis An acute, sometimes fatal disease characterized by destruction of skeletal muscle.

rheumatic fever An inflammatory disease that may develop as a delayed reaction to streptococcal infection of the upper respiratory tract.

rheumatoid arthritis A chronic, sometimes deforming destructive collagen disease that has an autoimmune component.

rheumatoid lungs Rheumatoid arthritis with emphasis on nonarticular changes; for example, pulmonary interstitial fibrosis, pleural effusion, and lung nodules.

rhinitis Inflammation of the mucous membranes of the nose.

rhinorrhea The free discharge of watery nasal fluid.

rhonchi Abnormal sounds heard on auscultation of a respiratory airway obstructed by thick secretions, muscular spasm, neoplasm, or external pressure.

rib One of the 12 pairs of elastic arches of bone forming a large part of the thoracic skeleton. The first seven ribs on each side are called *true ribs* because they articulate directly with the sternum. The remaining five ribs are called *false ribs;* the first three attach ventrally to the ribs, and the last two ribs are free at their ventral extremities and are called *floating ribs.*

ribonucleic acid A nucleic acid found in the nucleus and the cytoplasm of cells that transmits genetic instructions from the nucleus to the cytoplasm. In the cytoplasm, RNA functions in the assembly of proteins.

ribosome The "factory" of a cell where protein is synthesized.

ricin A potent protein cytotoxin derived from the beans of the castor plant *(Ricinus communis).*

right atrium One of the four chambers of the human heart; receives deoxygenated blood from the body through the vena cava and pumps it into the right ventricle.

right lymphatic duct A vessel that conveys lymph from the right upper quadrant of the body into the bloodstream in the neck at the junction of the right internal jugular and the right subclavian veins.

rigor mortis The rigid stiffening of skeletal and cardiac muscle shortly after death.

riot control agents Chemicals that can produce sensory irritation or disabling physical effects that disappear within a short time after termination of exposure.

Rocky Mountain spotted fever A serious tick-borne infectious disease characterized by chills, fever, severe headache, mental confusion, and rash.

rod A photoreceptor in the retina of the eye; it is responsible for noncolor vision in low-intensity light.

Romberg's test A test to evaluate stance and balance; performed by having the patient stand erect with the feet together and arms at the sides.

R-on-T phenomenon The occurrence of a ventricular depolarization during a vulnerable period of relative refractoriness.

root The lowest part of the tooth; it is covered by cementum.

rooting reflex A normal infant response elicited by touching or stroking the side of the cheek or mouth; this causes the infant to turn the head toward the stimulated side and to begin to suck.

rotation Movement of a structure about its axis.

rouleau formation An aggregation of red cells in what looks like a stack of coins or checkers.

round ligament The remains of the umbilical vein.

rubella A contagious viral disease characterized by fever, symptoms of mild upper respiratory tract infection, lymph node enlargement, and a diffuse, fine, red maculopapular rash; it is spread by droplet infection; also known as *German measles.*

rubeola An acute, highly contagious viral disease involving the respiratory tract; it is characterized by a spreading, maculopapular, cutaneous rash and occurs primarily in young children who have not been immunized; also known as *red measles.*

rule of nines A method to estimate burn injury that divides the total body surface area into segments that are multiples of 9%.

rupture of membranes Rupture of the amniotic sac; it usually occurs toward the end of the first stage of labor.

ruptured diaphragm A tear or break in the diaphragm, usually as a result of injury.

ruptured ovarian cyst A ruptured globular sac filled with fluid or semisolid material that develops in or on the ovary.

S prime A subsequent negative deflection in the QRS complex that extends below the baseline.

sacral bone A bone composed of the five segments of the vertebral column that are fused in the adult to form the sacrum; the segments are designated S1 to S5.

sacral promontory The projecting portion of the pelvis at the base of the sacrum.

sacral sparing The preservation of sensory or voluntary motor function of the perineum, buttocks, scrotum, or anus.

sacrum The large, triangular bone at the dorsal part of the pelvis; it is inserted like a wedge between the two hipbones.

saddle joint A joint that consists of two saddle-shaped articulating surfaces oriented at right angles to each other.

safe holding area An area away from the emergency scene that provides for safety.

sagittal plane An imaginary plane that runs vertically through the middle of the body, producing right and left sections.

salicylate Any one of several widely prescribed drugs derived from salicylic acid (e.g., aspirin).

salivary amylase A digestive enzyme found in saliva that begins the chemical digestion of carbohydrates.

salivary gland One of the three pairs of glands that empty their secretions into the mouth, thus aiding the digestive process.

salpingitis An inflammation or infection of the fallopian tube.

saltatory conduction Conduction in which action potentials jump from one node of Ranvier to the next node of Ranvier.

saphenous vein One of a pair of the longest veins in the body; it begins in the medial marginal vein in the dorsum of the foot and ends in the femoral vein.

sarcoidosis A chronic disorder of unknown origin characterized by the formation of lesions in the lung, spleen, liver, skin, and mucous membranes and in the lacrimal and salivary glands.

sarcolemma Part of a myofibril between adjacent Z lines.

sarcomere The contractile unit of skeletal muscle, which contains thick and thin myofilaments.

sarcoplasmic reticulum Endoplasmic reticulum of the muscle.

sarin A clear, colorless, and tasteless liquid that has no odor in its pure form; may be used as a nerve agent.

scabies A contagious parasitic skin infection characterized by superficial burrows and intense pruritus; caused by the mite *Sarcoptes scabiei.*

scanning A component of attention that refers to one's ability to review a large amount of sensory input rapidly. Different individuals have different capacities for scanning and may use various approaches and styles in their scanning.

scapula One of the pair of large, flat triangular bones that form the dorsal part of the shoulder girdle.

scene size-up An assessment of the scene to ensure scene safety for the paramedic crew, patient(s), and bystanders; a quick assessment to determine the resources needed to manage the scene adequately.

schizophrenia A group of disorders characterized by recurrent episodes of psychotic behavior.

school age Children 6 to 12 years of age.

Schwann cell A cell that forms a myelin sheath around each nerve fiber of the peripheral nervous system.

sciatic nerve A long nerve that originates in the sacral plexus and extends through the muscles of the thigh, leg, and foot with numerous branches.

sciatica Inflammation of the sciatic nerve.

sclera The opaque membrane covering the eyeball.

scleroderma A collagen vascular disease thought to result from the immune system stimulating certain cells (fibroblasts) that cause an increased production of collagen.

scoliosis A lateral curvature of the spine.

scrambling Movement over rough terrain that is not steep enough to require the use of a rope.

scrotum The sac of skin that contains the testes.

sebaceous gland A gland of the skin, usually associated with a hair follicle that produces sebum.

sebum The secretion of sebaceous glands; it prevents drying and protects against some bacteria.

second stage of labor The stage of labor measured from full dilation of the cervix to delivery of the newborn.

secondary assessment Consists of physical examination techniques, measurement of vital signs, an assessment of body systems, and the skillful use of examination equipment.

secondary bronchus A branch from a primary bronchus that conducts air to each lobe of the lungs.

secondary contamination Exposure to a hazardous substance whereby liquid and particulate substances are transferred easily to others by touching.

secondary epilepsy Epilepsy that can be traced to trauma, infection, a cerebrovascular disorder, or another illness that contributes to or causes the seizure disorder.

secondary follicle The follicle in which the secondary oocyte is surrounded by granulosa cells.

secondary polycythemia A condition of increased production of RBCs caused by reduced air pressure and low oxygen; may be a natural response to chronic hypoxia.

secondary tumor A malignant tumor that originates in one area of the body and spreads to another area of the body.

second-degree burn A burn injury that extends through the epidermis to the dermis (superficial partial thickness); it is considered a deep partial-thickness injury if it extends to the basal layers of the skin.

secretin The hormone that stimulates secretion of pancreatic juice.

secretion A general term for a substance produced inside a cell and released from the cell.

secretory phase The portion of the menstrual cycle extending from the time of formation of the corpus luteum after ovulation to the time when menstrual flow begins.

sedative-hypnotic A drug that reversibly depresses the activity of the central nervous system; these drugs are used chiefly to induce sleep and relieve anxiety.

seizure A temporary alteration in behavior or consciousness caused by abnormal electrical activity of one or more groups of neurons in the brain.

selectivity A component of attention that refers to a person's ability to pick or choose specific components of the sensory input that the person is reviewing and then focus on that input.

self-concept The accumulation of knowledge about one's self, including beliefs regarding personality traits, physical characteristics, abilities, values, goals, and roles.

self-contained breathing apparatus A respiratory protection device that provides an enclosed system of air.

self-esteem A person's overall evaluation or appraisal of his or her own worth.

self-neglect A type of elder abuse; behaviors of an older adult that intentionally threaten personal health or safety.

Sellick maneuver Cricoid cartilage pressure directed posteriorly to compress the trachea against the cervical vertebrae, thereby occluding the esophagus; this maneuver

is useful for limiting the risk of aspiration during an intubation procedure.

semen Male reproductive fluid.

semicircular canal A structure located in the inner ear that generates a nerve impulse when the head moves.

semi-Fowler position An inclined position with the upper half of the body raised by elevating the head of the bed or stretcher about 30 degrees to prevent reflux of gastric contents.

semilunar valve A valve with a half-moon shape, such as the aortic valve and the pulmonary valve.

seminal vesicle One of two glandular structures that empty into the ejaculatory ducts; its secretion is one of the components of semen.

semipermeable membranes A membrane that allows some fluids and substances to pass through it but not others, usually depending on size, shape, electrical charge, or other chemical properties.

senile dementia An organic mental disorder of the aged resulting from generalized atrophy of the brain with no evidence of cerebrovascular disease.

sensitization An acquired reaction in which specific antibodies develop in response to an antigen.

sensory Pertaining to a part or all of the sensory nerve network of the body.

sensory layer The portion of the retina that contains rods and cones; also known as the *sensory retina.*

sensory neuron A neuron that transmits impulses to the spinal cord and brain from all parts of the body.

sensory retina See *sensory layer*.

separation anxiety A normal period during development in which a child experiences anxiety when separated from the primary caregiver.

sepsis Infection.

septic arthritis A condition that results from direct invasion of the joint space by various microorganisms; also known as *infectious arthritis*.

septic shock A form of shock that most often results from a serious systemic bacterial infection.

septicemia Systemic infection in which the pathogens are present in the bloodstream, having spread from an infection in any part of the body.

septum A thin wall dividing two cavities or masses of soft tissue.

serotonin A hormone and neurotransmitter released from platelets when blood vessel walls are damaged.

serotonin syndrome A potentially life-threatening drug reaction; most often occurs when two or more drugs that affect serotonin levels are taken together.

serous membrane One of the many thin sheets of tissue that line closed cavities of the body, such as the pleura lining the thoracic cavity, the peritoneum lining the abdominal cavity, and the pericardium lining the sac that encloses the heart.

serous pericardium The thin inner layer of the pericardium that surrounds the heart.

serum Blood plasma without its clotting factors.

sexual abuse Nonconsensual sexual contact of any kind.

sexual assault The forcible perpetration of an act of sexual contact on the body of another person, male or female, without his or her consent.

sexually transmitted disease Refers to a group infections that are passed from one person to another through sexual contact.

shaken baby syndrome A serious form of child abuse that describes injuries to infants that occur after being violently shaken.

shingles An acute infection caused by reactivation of the latent varicella-zoster virus; it is characterized by painful vesicular eruptions that follow the underlying route of cranial or spinal nerves inflamed by the virus; also known as *herpes zoster*.

shipping papers Descriptions of the hazardous materials that include the substance name, classification, and United Nations identification number.

shock An abnormal condition of inadequate blood flow to the body's peripheral tissues that is associated with life-threatening cellular dysfunction; also known as *hypoperfusion.*

short bones Bones that are approximately as broad as they are long, such as the carpal bones of the wrist and the tarsal bones of the ankle.

shoulder dystocia An obstacle to delivery that occurs when the fetal shoulders press against the maternal symphysis pubis, blocking shoulder delivery.

shoulder girdle The encircling bony structure that supports the upper limbs; also known as the *pectoral girdle.*

shoulder presentation The presentation that results when the long axis of the fetus lies perpendicular to that of the mother; also known as *transverse presentation.*

shunt A tube or device surgically implanted in the body to redirect body fluid from one cavity or vessel to another.

shunting The redirection of a flow of body fluid from one cavity or vessel to another.

sibling rivalry Jealousy or competitiveness between brothers and sisters.

sickle cell anemia An inherited blood disorder that affects red blood cells; the most common type of sickle cell disease.

sickle cell crisis An acute episodic condition that occurs in individuals with sickle cell anemia.

sickle cell disease A debilitating and unpredictable recessive genetic illness that produces an abnormal type of hemoglobin with an inferior oxygen-carrying capacity.

side effect An often unavoidable and undesirable effect of using therapeutic doses of a drug; actions or effects other than those for which the drug was originally given.

sighing An occasional deep, audible inspiration that usually is insignificant.

sigmoid colon The segment of the colon that extends from the end of the descending colon in the pelvis to the juncture with the rectum.

significant medical history A patient's medical background that may offer insight into the patient's current problem.

silicosis A lung disorder caused by continued long-term inhalation of the dust of an inorganic compound, silicon dioxide; the disorder is characterized by dyspnea and the development of nodular fibrosis in the lungs.

simplex mode A communications mode with the ability to transmit or receive in one direction at a time. Simultaneous transmission cannot occur.

sinoatrial node An area of specialized heart tissue that generates the cardiac electrical impulse.

sinus One of several cavities in the bones of the skull that connect to the nasal cavities by small channels.

sinus headache A headache characterized by pain in the forehead, nasal area, and eyes.

sinusitis Inflammation of one or more paranasal sinuses.

sinusoid A form of terminating blood channel, somewhat larger than a capillary, lined with reticuloendothelial cells.

six cardinal fields of gaze A test to evaluate extraocular muscle function; performed by having the patient visually track an object in six visual fields in an H pattern.

size-up See *scene size-up*.

skeletal muscle Muscle tissue that appears microscopically to consist of striped myofibrils; also known as *striated muscle* and *voluntary muscle.*

skeletal system The body system comprised of bones, muscles, tendons and ligaments, and articulating surfaces (e.g., joints, bursa, disks).

Skene's glands The largest of the glands that open into the urethra of women.

skin graft A portion of skin implanted to cover areas where skin has been lost through burns or injury or by surgical removal of diseased tissue.

slander Verbally making false statements to others about a person, knowing that the statements are false, and with malicious intent or reckless disregard for their falsity.

sleep apnea A sleep disorder characterized by periods in which attempts to breathe are absent.

slipped capital femoral epiphysis A separation of the ball of the hip joint from the femur at the upper, growing end (growth plate) of the bone.

slough To shed or cast off; tissue that has been shed.

slow reactive substance of anaphylaxis A bronchoconstrictor mediator released from mast cells; it increases the production of prostaglandins.

small intestine The longest portion of the digestive tract; it is divided into the duodenum, jejunum, and ileum.

smallpox A highly contagious viral disease characterized by fever, prostration, and a vesicular, pustular rash.

smooth muscle One of two kinds of muscle; it is composed of elongated, spindle-shaped cells in muscles not under voluntary control, such as smooth muscle of the intestines, stomach, and other visceral organs; also known as *visceral muscle, involuntary muscle,* and *nonstriated muscle.*

sniffing position The patient position used during orotracheal intubation in which the patient's neck is flexed at C5 and C6 and the head is extended at C1 and C2.

SOAP format A memory aid used to organize written and verbal patient reports; it includes subjective data, objective data, assessment data, and plan of patient management.

sodium bicarbonate An antacid, electrolyte, and urinary alkalinizing agent.

sodium ions Ions involved in acid-base balance, water balance, nerve impulse transmission, and muscle contraction.

sodium-potassium exchange pump The biochemical mechanism that uses energy derived from adenosine triphosphate to achieve the active transport of potassium ions opposite to that of sodium ions.

soft palate The posterior muscular portion of the palate, which forms an incomplete septum between the mouth and the oropharynx and between the oropharynx and the nasopharynx.

solutes Substances dissolved in solution.

soman A clear, colorless, tasteless liquid with a slight camphor odor; may be used as a nerve agent.

somatic nervous system The part of the nervous system composed of nerve fibers that send impulses from the central nervous system to skeletal muscle.

somatic pain Pain that arises from skeletal muscles, ligaments, vessels, or joints.

somatization disorder A condition in which an individual has complaints (lasting several years) of various physical problems for which no physical cause can be found.

somatoform disorder Any of a group of neurotic disorders characterized by symptoms suggesting physical illness or disease for which there are no organic or physiological causes.

somatomotor Referring to cranial nerves that control the skeletal muscles through motor neurons.

somatomotor nerves Motor nerves to the skeletal muscles.

somatomotor neurons Neurons that innervate skeletal muscles.

spasm An involuntary muscle contraction of sudden onset.

spastic colon Abnormally increased motility of the small and large intestines, generally associated with stress; also known as irritable bowel syndrome.

special emergency radio service A specific group of radio frequencies designated by the Federal Communications Commission for use by emergency agencies.

sperm See *spermatozoon*.

spermatic cord A structure that extends from the deep inguinal ring in the abdomen to the testes; each cord comprises arteries, veins, lymphatics, nerves, and the excretory duct of the testis.

spermatogenesis The process of development of spermatozoa.

spermatozoa See *spermatozoon*.
spermatozoon The male sex cell, composed of a head and tail; it contains genetic information transmitted by the male.
sphenoid bone The bone at the base of the skull anterior to the temporal bones and the basilar part of the occipital bone.
sphenoid sinus One of a pair of cavities in the sphenoid bone that are lined with mucous membrane continuous with that of the nasal cavity.
sphincter Ring-shaped muscle.
sphygmomanometer The device used to measure blood pressure.
spina bifida A congenital defect in which part of one or more vertebrae fail to develop completely, leaving a portion of the spinal cord exposed.
spinal cord shock See *neurogenic shock*.
spinal cord tumor A benign or malignant tumor that originates in the cells within or next to the spinal cord.
spinal ganglia The structures that contain the cell bodies of sensory neurons; also known as *dorsal root ganglia.*
spinal nerve One of 31 pairs of nerves formed by the joining of the dorsal and ventral routes that arise from the spinal cord.
spinal shock A temporary loss of all types of spinal cord function distal to a cord injury.
spinal stenosis Narrowing of the spinal canal.
spinous process A part of the vertebrae that projects backward from the vertebral arch, giving attachment to muscles of the back.
spleen A large, highly vascular lymphatic organ situated in the upper part of the abdominal cavity between the stomach and the diaphragm; it responds to foreign substances in the blood, destroys worn-out erythrocytes, and is a storage site for red blood cells.
splenomegaly An abnormal enlargement of the spleen.
spondylosis A condition of the spine characterized by fixation or stiffness of the vertebral joint.
spontaneous abortion An abortion that usually occurs before 12 weeks' gestation; the lay term is *miscarriage.*
spontaneous pneumothorax A condition that results when a subpleural bleb ruptures, allowing air to enter the pleural space from within the lung.
sprain A partial tearing of a ligament caused by a sudden twisting or stretching of a joint beyond its normal range of motion.
sputum Material coughed up from the lungs and expectorated from the mouth.
squelch A radio receiver circuit used to suppress the audio portion of unwanted radio signals or radio noises below a predetermined carrier strength level.
ST segment The early part of repolarization in the electrocardiogram of the right and left ventricles.
ST-segment elevation myocardial infarction (STEMI) Myocardial infarction characterized by ST-segment elevation greater than 1 mm (0.1 mV) in two or more adjacent limb leads or any two contiguous chest leads.
staging area A designated area where incident-assigned vehicles are directed and held until needed.
stance The position of the body while standing.
standing orders Specific treatment protocols used by prehospital emergency care providers in the absence of online (direct) medical direction when delay in treatment would harm the patient.
stapes The smallest of the three ossicles in the middle ear.
staphylococcal infection An infection caused by any one of several pathogenic species of *Staphylococcus,* commonly characterized by the formation of abscesses of the skin or other organs.
starch The principal molecule used for the storage of food energy in plants.
Starling hypothesis The concept that describes the movement of fluid back and forth across the capillary wall (net filtration).
Starling's law of the heart A rule that the force of the heartbeat is determined by the length of the fibers making up the myocardial walls.
stasis A disorder in which the normal flow of fluid through a vessel of the body is slowed or halted.
status asthmaticus A severe, prolonged asthma exacerbation that has not been terminated with repeated doses of bronchodilators.
status epilepticus Continuous seizure activity lasting 30 minutes or longer, or a recurrent seizure without an intervening period of consciousness.
stellate wound A star-shaped wound.
stenosis Abnormal constriction or narrowing of an opening or passageway in a body structure.
sternal angle The point at which the manubrium joins the body of the sternum; also known as the *angle of Louis.*
sternoclavicular joint The double gliding joint between the sternum and the clavicle.
sternomanubrial joint See *sternal angle*.
sternum The elongated, flattened bone forming the middle portion of the thorax.
steroid A member of a large family of lipids, including some reproductive hormones, vitamins, and cholesterol.
steroid hormones Hormones that are synthesized by endocrine cells from cholesterol, including cortisol, aldosterone, estrogen, progesterone, and testosterone.
stimulant A drug that enhances or increases body function or activity.
Stokes-Adams syndrome A condition characterized by sudden episodes of loss of consciousness caused by incomplete heart block; seizures may accompany the episodes.
stoma A surgically created artificial opening of an internal organ on the surface of the body.
stomach The major organ of digestion, located in the right upper quadrant of the abdomen.
strain An injury to the muscle or its tendon from overexertion or overextension.
stratum basale The innermost layer of the epidermis.

stratum corneum The most superficial layer of the epidermis.

stratum granulosum The layer of the epidermis that lies just beneath the stratum corneum except in the palms of the hands and soles of the feet, where it lies just beneath the stratum lucidum.

stratum lucidum The layer of the epidermis that lies just beneath the stratum corneum; it is present only in the thick skin of the palms of the hands and soles of the feet.

stratum spinosum The layer of the epidermis that lies on top of the stratum basale and beneath the stratum granulosum.

strep throat An infection of the throat caused by streptococcal bacteria.

streptococcal infection An infection caused by pathogenic bacteria from one of several species of the genus *Streptococcus* or their toxins.

stress A nonspecific mental or physical strain caused by any emotional, physical, social, economic, or other factor that initiates a physiological response.

stressor Any factor that causes wear and tear on the physical or mental resources of the body.

stretch mark See *stria*.

stria A streak or linear scar that often results from rapidly developing tension in the skin; also known as a *stretch mark*.

striated Having striped or parallel lines, as in skeletal muscle.

striated muscle See *skeletal muscle*.

stridor An abnormal, high-pitched musical sound caused by obstruction in the trachea or larynx.

stroke See *cerebrovascular accident*.

stroke volume The volume of blood ejected from one ventricle in a single heartbeat.

stupor A state of lethargy and unresponsiveness in which a person seems unaware of his or her surroundings.

stylet A thin metal probe for inserting into or passing through a needle, tube, or catheter; it sometimes is used to change the configuration of an endotracheal tube.

styloid process A bony projection.

subarachnoid hematoma A collection of blood or fluid in the subarachnoid space.

subarachnoid hemorrhage Bleeding within the subarachnoid space.

subarachnoid space The area below the arachnoid membrane but above the pia matter that contains cerebrospinal fluid.

subclavian vein The continuation of the axillary vein in the upper body; it extends from the lateral border of the first rib to the sternal end of the clavicle, where it joins the internal jugular to form the brachiocephalic vein.

subcutaneous emphysema The presence of air in the subcutaneous tissues.

subcutaneous injection The introduction of medicine through a hypodermic needle into the subcutaneous tissue beneath the skin.

subcutaneous tissue The adherent layer of adipose tissue just below the dermal layer; also known as the hypodermis.

subdural hematoma A collection of blood in the subdural space.

subdural space The space between the dura mater and arachnoid.

subendocardial infarction See *transmural infarction*.

subgaleal hematoma A collection of blood beneath the strong sheet of fibrous connective tissue that joins the frontal and occipitofrontal muscles.

sublingual route The route of medication administration in which the medication is placed under the tongue so that the tablet dissolves in salivary secretions.

subluxation A partial dislocation.

submersion An incident in which a person experiences some swimming-related distress that is sufficient to require support in the prehospital setting and transportation to a medical facility for further observation and treatment.

substrate A substance acted upon and changed by an enzyme in any chemical reaction.

sucking reflex A normal infant response in which touching the infant's lips with the nipple of a breast or bottle causes involuntary sucking movements.

sudden death A death that occurs within the first 2 hours after the onset of illness or injury.

sudden infant death syndrome The unexpected and sudden death of an apparently normal and healthy infant that occurs during sleep.

sudoriferous gland See *sweat gland*.

suicide The act of a human being intentionally causing his or her own death.

summation The combined effects of two drugs that equal the sum of the individual effects of each agent.

superficial burn A burn injury where only a superficial layer of epidermal cells is destroyed; also known as a *first-degree burn*.

superficial frostbite A cold injury with at least some minimal tissue loss; it usually involves the dermis and shallow subcutaneous layers.

superficial pain Pain that arises from the skin or mucous membrane.

superficial reflexes Reflexes elicited by sensory afferents from skin.

superior Situated above or higher than a point of reference in the anatomical position.

superior vena cava The vein that returns blood from the head and neck, upper limbs, and thorax to the right atrium.

supination Rotation of the forearm so that the anterior surface is up.

supine The position in which the patient is lying on the back (face up).

supine hypotension syndrome Hypotension that occurs in pregnant women who are in a supine position; it

results when the uterus compresses the inferior vena cava, decreasing cardiac filling and cardiac output.

suprasternal notch The superior margin of the manubrium, which can be felt easily at the anterior base of the neck; also known as the *jugular notch.*

surface tension The tendency of the surface of a liquid to minimize the area of its surface by contracting.

surfactant Lipoproteins that reduce the surface tension of pulmonary fluids.

suspensory ligament The band of peritoneum that extends from the ovary to the body wall; it contains the ovarian vessels and nerves.

suture A border or joint between two bones of the cranium.

sweat gland A structure that produces sweat or viscus organic secretions; also known as a *sudoriferous gland.*

sympathetic nervous system A subdivision of the autonomic nervous system that usually is involved in preparing the body for physical activity.

sympatholytic Antiadrenergic; blocking transmission of impulses from the adrenergic postganglionic fibers to effector organs or tissues.

sympathomimetic A pharmacological agent that mimics the effects of sympathetic nervous system stimulation of organs and structures by acting as an agonist or by increasing the release of the neurotransmitter norepinephrine at postganglionic nerve endings.

sympathy The expression of one's feelings about another person's problem.

symphysis A cartilaginous joint.

symphysis pubis The slightly movable, interpubic joint of the pelvis; it consists of two bones separated by a disk of fibrocartilage and connected by two ligaments; also known as the pubic symphysis.

synapse Functional membrane-to-membrane contact of a nerve cell with another nerve cell, muscle cell, gland cell, or sensory receptor; it functions in transmitting action potentials from one cell to another.

synaptic cleft The space between the presynaptic and postsynaptic membranes.

synaptic vesicle A secretory vesicle in the presynaptic terminal that contains neurotransmitter substances.

synchondrosis A cartilaginous joint between two immovable bones, such as the symphysis pubis, the sternum, and the manubrium.

syncope A brief lapse in consciousness caused by transient cerebral hypoxia.

syncytium Cardiac muscle cells that are bound together so tightly and their membranes are so permeable to electrical impulse that they act as a mass of merged cells or a single cell.

syndesmosis A fibrous articulation in which two bones are connected by interosseous ligaments.

synergism The combined action of two drugs that is greater than the sum of each agent acting independently.

synergist A muscle that works with other muscles to cause movement.

synovial fluid A thin, lubricating film that allows considerable movement between articulating bones.

synovial joint See *joint*.

synovial membrane The inner layer of an articular capsule that surrounds a freely movable joint.

syphilis A sexually transmitted disease characterized by distinct stages of effects over a period of years; any organ system may be involved.

system Interconnected functions or organs in which a stimulus or an action in one area affects all other areas.

systemic circulation Blood flow from the left ventricle to all parts of the body and back to the right atrium.

systemic lupus erythematosus A chronic inflammatory disease that affects many systems of the body; it is characterized by severe vasculitis, renal involvement, and lesions of the skin and nervous system.

systemic pressure Pressure generated by the left side of the heart.

systolic blood pressure The blood pressure measured during the period of ventricular contraction.

T lymphocytes The lymphocytes responsible for cell-mediated immunity.

T tubule Tubelike invagination of the sarcolemma that conducts action potentials toward the center of the cylindrical muscle fibers.

T wave A deflection in the electrocardiogram after the QRS complex, representing ventricular repolarization.

tabes dorsalis An abnormal condition characterized by the slow degeneration of all or part of the spinal cord and the progressive loss of peripheral reflexes.

tabun A clear, colorless, tasteless liquid with a faint fruity odor; may be used as a nerve agent.

tachycardia A heart rate that exceeds 99 beats per minute.

tachyphylaxis A phenomenon in which the repeated administration of some drugs results in a significant decrease in their effectiveness.

tachypnea A persistent respiratory rate that exceeds 20 breaths per minute.

tactical EMS Emergency medical services provided by EMS personnel who are specially trained and equipped to provide prehospital emergency care in tactical environments.

tactical patient care Patient care activities that occur inside the scene perimeter, or hot zone, of a dangerous scene.

tactical retreat Leaving the scene when danger is observed or when violence or indicators of violence are displayed; requires immediate and decisive action.

talus The second largest tarsal bone; the ankle bone.

tardive dyskinesia An abnormal condition characterized by involuntary, repetitious movements of the muscles of the face, limbs, and trunk.

tarsal Pertaining to the area of articulation between the foot and the leg.

tarsal bones Bones of the ankle.

taste bud Any one of many peripheral taste organs distributed over the tongue and roof of the mouth.

TB disease Active tuberculosis.

teachable moment The time after an injury has occurred when the patient and observers remain acutely aware of what has happened and may be more receptive to being taught ways that the event or illness could have been prevented.

telecommunicator A person trained in public safety telecommunications; the term applies to call takers, dispatchers, radio operators, data terminal operators, or any combination of such functions in a public service answering point.

telemedicine Refers to technological communications that allow for the transmission of photographs, video, and other information to be sent directly from the scene to a hospital for physician evaluation and consultation.

telemetry The transmission and reception of physiological data by radio or telephone; for example, electrocardiograms.

temperament A person's style of behavior; the way the person interacts with the environment. It is the basis on which children develop relationships.

temporal bone One of a pair of large bones that form part of the lower cranium and that contain various cavities and recesses associated with the ear.

temporal lobe The lateral region of the cerebrum; it contains the center for smell and some association areas for memory and learning.

temporomandibular joint dysfunction Acute or chronic inflammation in the temporomandibular joint.

ten code (10 code) A code sometimes used in radio communications that uses the number 10 plus another number to relay a particular message.

tendon A band or cord of dense connective tissue that connects muscle to bone or other structures; it is characterized by strength and nonstretchability.

tendonitis An inflammatory condition of a tendon, usually caused by a sprain.

tenosynovitis Inflammation of a tendon sheath.

tension headache A headache caused by muscle contractions of the face, neck, and scalp.

tension pneumothorax An accumulation of air or gas in the pleural cavity that can lead to collapse of the lung.

teratogenic Any substance, agent, or process that interferes with normal prenatal development.

term A pregnancy that has reached 40 weeks' gestation.

terminal bronchiole The end of the conducting airway.

terminal drop A theory that a decline in intelligence in older adulthood may be caused by a person's conscious or unconscious perception of coming death.

terminally ill patients Patients with advanced stage of disease with an unfavorable prognosis and no known cure.

termination of action The point at which a drug effect is no longer seen.

tertiary segmental bronchus The bronchus that extends from the secondary bronchus and conducts air to each lobule of the lung.

testes The male gonads, which produce the male sex cells, or sperm.

testicular mass An enlargement or growth on one or both testicles.

testicular torsion A condition in which a testicle twists on its spermatic cord, disrupting its own blood supply.

testosterone The male sex hormone.

tetanus An acute, potentially fatal infection of the central nervous system caused by the tetanus bacillus *Clostridium tetani;* it is characterized by muscle spasms and convulsions.

tetany The involuntary contraction of skeletal muscles.

tetralogy of Fallot A congenital cardiac anomaly that consists of four defects: pulmonic stenosis, ventricular septal defect, malposition of the aorta so that it rises from the septal defect or the right ventricle, and right ventricular hypertrophy.

thalamus Tissue located just above the hypothalamus; it helps to produce sensations, associates sensations with emotions, and plays a part in arousal.

therapeutic abortion The legal termination of a pregnancy for reasons of maternal well-being.

therapeutic action The desired, intended action of a drug.

therapeutic communications A planned, deliberate, professional act that involves the use of communications techniques to achieve two purposes: (1) a positive relationship with a patient and (2) a shared understanding of information for desired patient care goals.

therapeutic index A measurement of the relative safety of a drug.

therapeutic range The range of plasma concentrations that is most likely to produce the desired drug effect with the least likelihood of toxicity; the range between minimal effective concentration and toxic level.

thermogenesis Production of heat, especially by the cells of the body.

thermolysis The dissipation of heat by means of radiation, evaporation, conduction, or convection.

thiazide A group of diuretics that are moderately effective in lowering blood pressure.

third stage of labor The stage of labor that begins with delivery of the infant and ends when the placenta has been expelled and the uterus has contracted.

third ventricle The ventricle located in the center of the diencephalon between the two halves of the thalamus.

third-degree burn A burn injury in which the entire thickness of the epidermis and dermis is destroyed.

thoracentesis Puncturing of pleural space.

thoracic aorta The large upper portion of the descending aorta; it supplies many parts of the body such as the heart, ribs, chest muscles, and stomach.

thoracic cavity The area of the body enclosed by the ribs.

thoracic duct The common trunk of all the lymphatic vessels of the body except those on the right side of the

head and neck, the thorax, right upper limb, right lung, right side of the heart, and the diaphragmatic surface of the liver.

thoracic vertebrae The 12 bony segments of the spinal column of the upper back, designated T1 to T12.

thoroughfare channel The channel for blood through a capillary bed from an arteriole to a venule.

threatened abortion An abortion diagnosed when a patient has some uterine bleeding with an intrauterine pregnancy in which the internal cervical os is closed; it may stabilize and end in normal delivery or progress to an incomplete or complete abortion.

threshold potential The value of the membrane potential at which an action potential is produced as a result of depolarization in response to a stimulus.

thrill A fine vibration felt by an examiner's hands over the site of an aneurysm or on the pericardium.

thrombectomy The removal of a thrombus from a blood vessel.

thrombin An enzyme formed in plasma as part of the clotting process; it causes fibrinogen to change to fibrin, which is essential in the formation of a clot.

thrombocytes Cell fragments.

thrombocytopenia An abnormal hematological condition in which the number of platelets is reduced; the most common cause is a bleeding disorder.

thromboembolism A condition in which a blood vessel is blocked by an embolus carried in the bloodstream from the site of formation of the clot.

thrombogenesis Clot formation.

thrombolytic agent A drug that dissolves clots after their formation by promoting the digestion of fibrin.

thrombophlebitis See *phlebitis*.

thrombosis An abnormal formation of a thrombus within a blood vessel of the body.

thromboxanes Antagonistic prostaglandin derivatives that are synthesized and released by degranulating platelets, causing vasoconstriction and promoting the degranulation of other platelets.

thrombus An aggregation of platelets, fibrin, clotting factors, and the cellular elements of the blood attached to the interior wall of a vein or artery, which sometimes occludes the lumen of the vessel.

thymectomy Excision of the thymus.

thymus A single, unpaired gland located in the mediastinum; the primary central gland of the lymphatic system.

thyroid cartilage The largest laryngeal cartilage; it forms the laryngeal prominence, or Adam's apple.

thyroid membrane The fibrous membrane that joins the hyoid and the thyroid cartilages.

thyroid storm A life-threatening form of hyperthyroidism.

thyrotoxicosis A term that refers to any toxic condition that results from thyroid hyperfunction.

tibia The second longest bone of the skeleton; it is located on the medial side of the lower leg.

tibial tuberosity A large, oblong elevation at the proximal end of the tibia that attaches to the ligament of the patella.

tick paralysis A rare, progressive, reversible disorder caused by several species of ticks that release a neurotoxin that causes weakness, incoordination, and paralysis.

tidal volume The volume of gas inhaled or exhaled in a single, resting breath.

tinea A group of fungal skin diseases characterized by itching and scaling and sometimes by painful lesions.

tinnitus A ringing sound in the ears.

tissue binding A type of drug reservoir in which drug pooling occurs in fat tissue and bone.

toddler A child 1 to 3 years of age.

tolerance A physiological response that requires that a drug dosage be increased to produce the same effect formerly produced by a smaller dose.

tone The audio signal or carrier wave of controlled amplitude and frequency used for equipment control purposes or to selectively signal a receiver, such as activating a pager; tones are measured in hertz.

tonic-clonic seizure A generalized seizure involving the entire body; also known as *a grand mal seizure*.

tonsil A large collection of lymphatic tissue beneath the mucous membrane of the oral cavity and pharynx.

tonsillectomy Surgical removal of the tonsils.

tonsillitis Inflammation of the tonsils.

torr A measurement in millimeters of mercury.

torsades de pointes An unusual bidirectional ventricular tachycardia.

total body water All the water within the body, including intracellular and extracellular water and the water in the gastrointestinal and urinary tracts.

total lung capacity The sum of the inspiratory and expiratory reserve volumes plus the tidal volume and residual volume.

total pressure The combination of pressures exerted by all the gases in any mixture of gas.

Tourette's syndrome An abnormal condition characterized by facial grimaces, tics, and involuntary arm and shoulder movements.

toxic level The plasma concentration at which a drug is likely to produce serious adverse effects.

toxic shock syndrome A severe, acute disease caused by infection with strains of *Staphylococcus aureus*.

toxidromes Clinical syndromes grouped together for the successful recognition of poisoning patterns.

toxin A poison usually produced by or occurring in a plant or microorganism.

toxoid A toxin that has been treated with chemicals or with heat to reduce its toxic effects but that retains its antigenic power.

trachea A cylindrical tube in the neck composed of cartilage and membrane; it conveys air to the lungs.

tracheal stenosis Constriction of the trachea.

tracheitis A bacterial infection of the upper airway and subglottic trachea.

tracheostomy An opening through the neck into the trachea through which an indwelling tube may be inserted.

trade name The trademark name of a drug, designated by the drug company that sells the medication.

tragus A projection of the cartilage of the auricle at the opening of the external auditory meatus.

transceiver A combination transmitter and receiver with a switching circuit or duplexer to use a single antenna.

transcutaneous cardiac pacing The use of an artificial pacemaker to substitute for a natural pacemaker of the heart that is blocked or dysfunctional. In the prehospital setting a transcutaneous pacemaker is used to treat symptomatic bradycardia, heart block associated with reduced cardiac output that is unresponsive to atropine, pacemaker failure, and asystole.

transection A complete or incomplete lesion of the spinal cord.

transfusion hepatitis Hepatitis that results from a transfusion with infected blood.

transient dysphagia A temporary impairment of speech.

transient ischemic attack An acute episode of temporary neurological dysfunction resulting from focal cerebral ischemia; also called a "mini stroke."

translaryngeal cannula ventilation An advanced airway procedure that provides high-volume, high-pressure oxygenation of the lungs through cannulation of the trachea below the glottis; also known as needle percutaneous transtracheal ventilation and needle cricothyrotomy.

transmembrane potential The difference in electrical charge between inside and outside the plasma membrane.

transmitted nonspecific urethritis A sexually transmitted disease characterized by inflammation or infection of the urethra in which the cause is not defined; also known as nongonococcal urethritis.

transmural infarction A myocardial infarction that extends through the full thickness of the myocardium, including the endocardium and epicardium.

transudate A fluid passed through a membrane as a result of a difference in hydrostatic pressure.

transverse At right angles to the long axis of any common part.

transverse colon The segment of the colon that extends from the end of the ascending colon at the hepatic flexure on the right side across the midabdomen to the beginning of the descending colon at the splenic flexure on the left side.

transverse plane An imaginary plane that divides the body into top and bottom or superior and inferior sections; also known as the *horizontal plane.*

transverse presentation See *shoulder presentation*.

transverse process The bony segment that extends laterally from each side of the vertebral arch.

trauma An injury caused by a transfer of energy from some external source to the human body.

trauma index An early measurement that used a numerical injury rating system based on a patient's injured body region, type of injury, and cardiovascular, central nervous system, and respiratory status.

trauma score An injury severity index used to predict the outcome for patients with blunt or penetrating injuries.

traumatic asphyxia A severe crushing injury to the chest and abdomen that causes an increase in intrathoracic pressure. The increased pressure forces blood from the right side of the heart into the veins of the upper thorax, neck, and face.

traumatic hyphema See *hyphema*.

traumatic iridoplegia Traumatic dilation or, less commonly, constriction of the pupil.

treatment protocols Guidelines that define the scope of prehospital intervention practiced by emergency care providers.

Trendelenburg's position A position in which the head is low and the body and legs are on an inclined plane.

triage A method used to sort or categorize patients according to severity of injury.

triaxial reference system Three intersecting lines of reference used in standard limb leads.

trichomoniasis A vaginal infection caused by the protozoan *Trichomonas vaginalis;* it is characterized by itching, burning, and a frothy, pale yellow to green vaginal discharge.

tricuspid valve The valve located between the right atrium and ventricle.

trigeminal nerve Either of the largest pair of cranial nerves, which are essential for chewing and the general sensibility of the face.

trigeminal neuralgia Infection or disease of the trigeminal nerve (cranial nerve V); also known as *central pain syndrome.*

triglyceride A compound consisting of a fatty acid and glycerol.

trigone The triangular smooth area at the base of the bladder between the openings of two ureters and that of the urethra.

trimester One of three periods of approximately 3 months into which pregnancy is divided.

triphosphate bond Energy sources for the muscles, nerves, and overall function of the body; an example is adenosine triphosphate.

triplets Three premature ventricular contractions in a row.

trismus Muscle spasms of the jaw.

trochanter One of the two bony projections at the proximal end of the femur that serve as the attachment point for various muscles.

trochlea The medial aspect of the humerus; it articulates with the ulna.

trophoblast A cell layer that forms the outer layer of the blastocyst, which erodes the uterine mucosa during implantation; it contributes to the formation of the placenta.

true rib See *rib*.
true vocal cord See *vocal cord*.
truncal obesity Obesity that preferentially affects or is isolated in the trunk of the body rather than the extremities.
trunking system A radio system consisting of base stations on different channels connected to each other with small computers that work with special mobile and portable signaling to allow multiple simultaneous conversations.
tubal ligation One of several sterilization procedures in which both fallopian tubes are blocked to prevent conception..
tubercle A nodule or small eminence, such as that on a bone or that produced by infection from tubercle bacilli.
tuberculosis A chronic granulomatous infection caused by *Mycobacterium tuberculosis;* it usually affects the lungs and generally is transmitted by inhalation or ingestion of infected droplets.
tuberosities Elevations or protuberances, especially of bones.
tuboovarian abscess An abscess involving the ovary and fallopian tube.
tularemia A serious illness that is caused by the bacterium *Francisella tularensis* found in animals (especially rodents, rabbits, and hares).
tunic One of the enveloping layers of a part; one of the coats of a blood vessel; one of the coats of the eye; one of the coats of the digestive tract.
tunica adventitia The outermost fibrous coat of a vessel or an organ that is derived from the surrounding connective tissue.
tunica intima The innermost coat of a blood vessel.
tunica media The middle coat, usually muscular, of an artery or other tubular structure.
turbinate The concha nasalis.
turgor The normal resiliency of the skin caused by the outward pressure of the cells and interstitial fluid.
Turner's sign Bruising of the skin of the flanks or loin in acute hemorrhagic pancreatitis; also known as Grey Turner's sign.
Turner's syndrome A chromosomal anomaly characterized by the absence of one X chromosome and characterized by short stature, undifferentiated gonads, and various other abnormalities.
tympanic membrane See *eardrum*.
tympany A hollow drumlike sound produced when a gas-containing cavity is percussed.
type 1 diabetes Diabetes that is characterized by inadequate production of insulin by the pancreas. It may occur any time after birth; requires lifelong treatment with insulin.
type 2 diabetes Diabetes that usually is characterized by a decrease in the production of insulin by the pancreatic beta cells and diminished tissue sensitivity to insulin (*insulin resistance*).
type and crossmatch A test used to determine the patient's ABO group and Rh type.
U wave The gradual deviation from the T wave in the electrocardiogram; thought to represent the final stage of repolarization of the ventricles.
ulceration The formation of a craterlike lesion on the skin or mucous membranes.
ulcerative colitis An inflammatory condition of the large intestine characterized by severe diarrhea and ulceration of the mucosa of the intestine.
ulna One of the bones of the forearm.
ulnar nerve entrapment An injury that occurs when the ulnar nerve in the arm becomes compressed.
ultrahigh frequency Radio frequency between 300 and 3000 MHz; the 460-MHz range commonly is used for emergency medical services communications.
umbilical cord A flexible structure connecting the umbilicus with the placenta and giving passage to the umbilical arteries and vein.
umbilicus The point on the abdomen at which the umbilical cord joined the fetal abdomen.
uncompensated shock A stage of shock that occurs when the body is no longer able to maintain systemic blood pressure.
unethical Conduct that fails to conform to moral principles, values, or standards.
unifocal premature ventricular complex A premature ventricular complex that originates from a single ectopic pacemaker site.
unipolar lead A lead composed of a single positive electrode and a reference point.
universal donor A person with blood of type O, Rh factor negative.
universal precautions Infection control practices in health care that are observed with every patient and procedure and that prevent exposure to blood-borne pathogens.
universal recipient A person with blood type AB who can receive any of the four types of blood.
unmyelinated axon A nerve fiber lacking a myelin sheath.
untoward effects Side effects that prove harmful to the patient.
upper airway Airway structures above the glottis.
upper esophageal sphincter The ring of muscle located at the superior opening of the esophagus that regulates the passage of materials into the esophagus.
upper respiratory tract infection Infection of the upper airway, affecting the nose, throat, sinuses, and larynx.
urea A nitrogen-containing waste product.
uremia The presence of excessive amounts of urea and other nitrogenous wastes produced in the blood.
uremic frost A pale, frostlike deposit of white crystals on the skin caused by kidney failure and uremia.
ureter One of a pair of tubes that carry the urine from the kidney into the bladder.
urethra A small tubular structure that drains urine from the bladder; in men, it also serves as a passageway for semen during ejaculation.
urethritis An inflammatory condition of the urethra.

uric acid A product of the metabolism of protein present in the blood and excreted in the urine.
urinary bladder The muscular, membranous sac in the pelvis that stores urine for discharge through the urethra.
urinary calculi Solid particles in the urinary system; commonly known as "kidney stones."
urinary retention The inability to urinate.
urinary tract infection An infection of one or more structures of the urinary tract.
urogenital triangle The anterior portion of the perianal region; it contains the openings of the urethra and vagina in the female and the root structures of the penis in the male.
urosepsis Septic poisoning caused by retention and absorption of urinary products in the tissues.
urticaria A pruritic skin eruption characterized by transient wheals of various shapes and sizes with well-defined margins and pale centers; also known as *hives.*
uterine Pertaining to the uterus.
uterine inversion A rare event in which the uterus turns inside out after birth.
uterine prolapse The falling or sliding of the uterus from its normal position in the pelvic cavity into the vaginal canal.
uterine rupture A rare event in which the wall of the uterus ruptures when it is unable to withstand the strain placed on it.
uterine tube One of a pair of ducts opening at one end into the uterus and the other end into the peritoneal cavity, over the ovary; also known as a *fallopian tube.*
uterosacral ligament A primary ligament that holds the uterus in place.
uterus The hollow, pear-shaped internal female organ of reproduction.
uvula The cone-shaped process hanging down from the soft palate that helps prevent food and liquid from entering the nasal cavities.
vagina The part of the female genitalia that forms a canal from the orifice through the vestibule to the uterine cervix.
vaginal bleeding The loss of blood from the uterus, cervix, or vagina.
vaginitis An inflammation of the vaginal tissues.
vagus nerve Either of the longest pair of cranial nerves essential for speech, swallowing, and the sensibilities and functions of many parts of the body.
vallecula A furrow between the glossoepiglottic folds on each side of the posterior oropharynx.
Valsalva maneuver A vagal maneuver used to slow the heart and decrease the force of atrial contraction by stimulating postganglionic parasympathetic nerve fibers in the wall of the atria and specialized tissues of the sinoatrial and atrioventricular nodes via the vagus nerve.
varicella An acute, highly contagious viral disease caused by a herpesvirus, varicella-zoster virus; it occurs primarily in young children and is characterized by crops of pruritic vesicular eruptions on the skin; also known as *chickenpox.*
varicella-zoster virus A member of the herpesvirus family that causes the disease varicella (chickenpox) and herpes zoster (shingles).
varicocele An abnormal enlargement of the veins that drain the testicle.
vas deferens See *ductus deferens*.
vascular tunic The choroid, ciliary body, and iris.
vasoconstriction A narrowing of the lumen of any blood vessel.
vasodilation An increase in the diameter of a blood vessel caused by inhibition of its constrictor nerves or stimulation of dilator nerves.
vasomotor Of or pertaining to the nerves and muscles that control the diameter of the lumen of blood vessels.
vasopressin mechanism The mechanism by which antidiuretic hormone secretion increases when blood pressure drops or plasma osmolarity increases; it reduces urine production and stimulates vasoconstriction.
vastus lateralis muscle The largest of the four muscles of the quadriceps femoris; it is situated on the lateral side of the thigh.
vein A vessel that carries blood toward the heart.
venereal disease A contagious disease usually acquired by sexual intercourse or genital contact.
venostasis Retardation of venous flow in a part.
venous capillary The ends of capillaries closest to venules.
venous sinus One of many sinuses that collect blood from the dura mater and drain it into the internal jugular vein.
ventilation The mechanical movement of air into and out of the lungs; makes respiration possible.
ventral root The nerve that conveys efferent nerve processes away from the spinal cord.
ventricle A small cavity; it usually refers to the right or left ventricle of the heart.
ventricular bigeminy A cardiac rhythm disturbance characterized by two ventricular beats in rapid succession followed by a longer interval.
ventricular fibrillation A cardiac dysrhythmia marked by rapid, disorganized depolarization of the ventricular myocardium.
ventricular quadrigeminy A cardiac dysrhythmia that occurs when every fourth complex is a premature ventricular complex.
ventricular tachycardia A tachycardia that usually originates in the Purkinje fibers.
ventricular trigeminy A cardiac dysrhythmia characterized by three ventricular beats in rapid succession followed by a longer interval.
ventrogluteal muscle The muscle that overlies the iliac crest and the anterior-superior iliac spine.
venule Small blood vessels that collect blood from the capillaries and join to form veins.
vermiform appendix See *appendix*.
vertebra Any one of 33 bones of the spinal column.

vertebral arch The dorsal, bony arch of a vertebra composed of the laminae and pedicles; it protects the spinal cord.

vertebral artery Each of the two arteries branching from the subclavian arteries.

vertebral body A bony disk that serves as the weight-bearing portion of the vertebra.

vertex presentation See *cephalic presentation*.

vertigo A sensation of faintness or an inability to maintain normal balance in a standing or seated position.

very high frequency Radio frequencies between 30 and 300 MHz (usually in the 150-MHz range). The very high frequency spectrum is divided further into high and low bands.

vesicants Chemicals with severely irritating properties that produce fluid-filled pockets on the skin and damage to the eyes, lungs, and other mucous membranes.

vesicular Pertaining to a blisterlike condition.

vesicular follicle The secondary follicle in which the oocyte attains its full size; also known as the *graafian follicle.*

vesiculation The formation of vesicles.

vestibular fold One of two folds of mucous membrane that stretch across the laryngeal cavity; it helps close the glottis; also known as the *false vocal cord.*

vestibule The portion of the inner ear adjacent to the oval window between the semicircular canals and the cochlea.

vestibule of the ear The middle region of the middle ear.

vestibule of the vagina The space behind the labia minora that contains the opening of the vagina, the urethra, and the vestibular glands.

vesicular breath sounds Breath sounds heard over most of the lung fields; the major normal breath sound.

vestibulocochlear nerve The eighth cranial nerve, formed by the cochlear and vestibular nerves; it extends to the brain.

viral hemorrhagic fevers A group of illnesses caused by several distinct families of viruses that include arenaviruses, filoviruses, bunyaviruses, and flaviviruses.

viral meningitis A syndrome generally associated with an existing systemic viral disease (e.g., enteroviral infection, herpesvirus infection, mumps, and, less commonly, influenza); also known as *aseptic meningitis*.

viral pneumonia An inflammation of the lungs caused by viral infection.

virulence The relative strength of a pathogen.

virus A minute, parasitic microorganism without independent metabolic activity that can replicate only within a cell of a living plant or animal host.

visceral Pertaining to internal organs enclosed within a body cavity, primarily the abdominal organs.

visceral pain Deep pain that arises from smooth vasculature or organ systems.

visceral pericardium The portion of the serous pericardium that covers the heart surface; also known as the *epicardium*.

visceral peritoneum The layer of peritoneum that covers the abdominal organs.

viscosity The physical property of a liquid. It is characterized by the degree of friction between its component molecules.

vital capacity The volume of gas moved on deepest inspiration and expiration, or the sum of the inspiratory reserve volume, the tidal volume, and the expiratory reserve volume.

vitamin An organic compound essential in small quantities for normal physiological and metabolic functioning of the body.

vitamin D A fat-soluble vitamin essential for the normal formation of bones and teeth and for absorption of calcium and phosphorus from the gastrointestinal tract.

vitamin K A fat-soluble compound essential for the synthesis of several related proteins involved in the clotting of blood.

vitreous humor The transparent, jellylike material that fills the space between the lens and the retina.

vocal cord One of two folds of elastic ligaments covered by mucous membrane that stretch from the thyroid cartilage to the arytenoid cartilage; vibration of the vocal cords is responsible for voice production; also known as a *true vocal cord.*

Volkmann's contracture A serious, persistent flexion contraction of the forearm and hand caused by ischemia.

voluntary Action originated or accomplished by a person's free will or choice.

voluntary muscle A muscle that is controlled consciously; see *skeletal muscle.*

vomer bone The bone forming the posterior and inferior part of the nasal septum.

vulva The external genitalia of the female.

VX A thick, amber-colored, odorless liquid that resembles motor oil; may be used as a nerve agent.

wandering atrial pacemaker The passive transfer of pacemaker sites from the sinus node to other latent pacemaker sites in the atria and atrioventricular junction.

water vapor pressure The partial pressure exerted by water molecules after they have been converted into a gas.

watt The unit of measurement of a transmitter's power output.

weapons of mass destruction Large conventional biological, nuclear, incendiary, chemical, or explosive weapons (B-NICE).

Wenckebach heart block Type I second-degree atrioventricular block; a progressive, beat-to-beat prolongation of the P-R interval that finally results in a nonconducted P wave; at this point, the sequence recurs.

Wernicke-Korsakoff syndrome A disease that results from chronic thiamine deficiency combined with an inability to use thiamine because of a heritable disorder or because of a reduction in intestinal absorption and metabolism of thiamine by alcohol.

Wernicke's encephalopathy A stage of Wernicke-Korsakoff syndrome that usually develops suddenly with the clinical manifestations of ataxia, nystagmus, disturbances of speech and gait, signs of neuropathy, stupor, or coma.

West Nile virus A potentially serious mosquito-borne illness that affects the central nervous system.

wheals Small areas of swelling of the skin that result from an allergic reaction.

wheeze A form of rhonchus characterized by a high-pitched, musical quality; it is caused by high-velocity airflow through narrowed airways.

whole-bowel irrigation An in-hospital method of GI decontamination; involves the rapid administration of large amounts of a specially balanced fluid to flush the GI tract.

windchill chart An index developed to calculate the cooling effects of the ambient temperature based on thermometer readings and the wind speed.

withdrawal syndrome A predictable set of signs and symptoms that occurs after a decrease in the usual dose of a drug or its sudden cessation.

xiphoid process The smallest of three parts of the sternum; it articulates caudally with the body of the sternum and laterally with the seventh rib.

years of productive life The calculation obtained by subtracting the victim's age at death from 65 (the average age of retirement).

yellow fever An acute infection transmitted by mosquitoes; it is characterized by headache, fever, jaundice, vomiting, and bleeding.

yellow marrow Specialized soft tissue (mainly adipose) found in the compact bone of most adult epiphyses.

Z line The delicate, membrane-like structure found at either end of a sarcomere.

zone of coagulation In a burn wound, the central area that has sustained the most intense contact with the thermal source; in this area coagulation necrosis of the cells has occurred and the tissue is nonviable.

zone of hyperemia An area in which blood flow is increased as a result of the normal inflammatory response to injury; it lies at the periphery of the zone of stasis.

zone of stasis The area of burn tissue that surrounds the critically injured area; it consists of tissue that is potentially viable despite the serious thermal injury.

zygomatic bone One of a pair of bones that forms the prominence of the cheek, the lower part of the orbit of the eye, and parts of the temporal bone; also known as the *zygomatic process*.

zygomatic process See *zygomatic bone*.

zygote The developing ovum from the time it is fertilized until it is implanted in the uterus as a blastocyst.

Appendix: Advanced Practice Procedures for Critical Care Paramedics

Some critically ill or injured patients require a level of care that is beyond the normal scope of the paramedic. For example, a patient may have special needs that require continuous medical supervision by one or more health professionals. These duties usually are provided by specialty personnel working in nursing, emergency medicine, respiratory care, and cardiovascular care. Supervision of the patient also can be provided by paramedics with advanced levels of training. This chapter addresses some of the advanced knowledge and patient care procedures that may be required of the paramedic who practices in critical care.

(Courtesy Keith and Margie Allen, O'Fallon, Mo.)

CRITICAL CARE AND CRITICAL CARE TRANSPORT

Critical care is a specialty within professional health care that deals with patients who have life-threatening illness or injury. Historically, this level of care has been provided primarily by physicians, physician assistants, specially trained registered nurses, respiratory therapists, clinical nurse specialists, and nurse practitioners. In recent years, providers of critical care have been expanded to include other health care professionals, including paramedics. Paramedics who practice in critical care settings (including critical care transport) have special training and advanced certifications. They also have additional experience working with critical care patients. Through this education, these paramedics are trained, credentialed, and become skilled in advanced practice procedures that may be performed infrequently by most other prehospital personnel.

Critical care transport (CCT) is also known as *specialty care transport* (SCT). The term is used to describe the delivery of medical services for a critically ill or injured patient during transport. Most paramedics who are members of a CCT team have completed a training program, such as Critical Care EMT-Paramedic (CCEMT-P), Critical Intensive Care Provider (CICP), and/or have other advanced certifications. These certification programs are focused on the most common and serious conditions that may require transport from a community hospital to a tertiary care facility.

SECTION ONE
Advanced Practice Procedures

Most educational programs for critical care include advanced training and skill procedures that are based on body systems (cardiac, respiratory, gastrointestinal, gastrourinary, renal, and neurologic), surgical airway management, and drug therapy. *It should be noted that the descriptions of the advanced practice procedures presented in this appendix are intended as an overview. All procedures carry significant complications and risks. In addition, all procedures require advanced training and authorization from the program's medical director. Any advanced procedures performed should have a written advanced protocol.* Advanced practice procedures that are described in this appendix include:

- Central venous cannulation
- Accessing the umbilical vein

- Arterial blood gas sampling
- Bladder catheterization
- Invasive hemodynamic monitoring
- Monitoring of an intraaortic balloon pump (IABP)
- Blood administration
- Use of IV infusion pumps
- Tube thoracostomy
- Pericardiocentesis

CENTRAL VENOUS CANNULATION

Central venous cannulation may be within the scope of paramedic practice in some critical care programs. Sites for central venous cannulation include the femoral vein, internal jugular vein, and subclavian vein (Figures 1 to 3). (Although the femoral vein is not truly a central vein, because the catheter is inserted in an area below the diaphragm, it is included in this section.)

The preparation for cannulation of the central vessels is similar to that for the peripheral veins (described in Chapter 14); however, attention to providing and maintaining a sterile field during placement is especially important. Several factors affect the success of central venous cannulation. Two of these factors are the position of the patient's body and the paramedic's knowledge of anatomy. The paramedic's familiarity with the procedure also is a key factor.

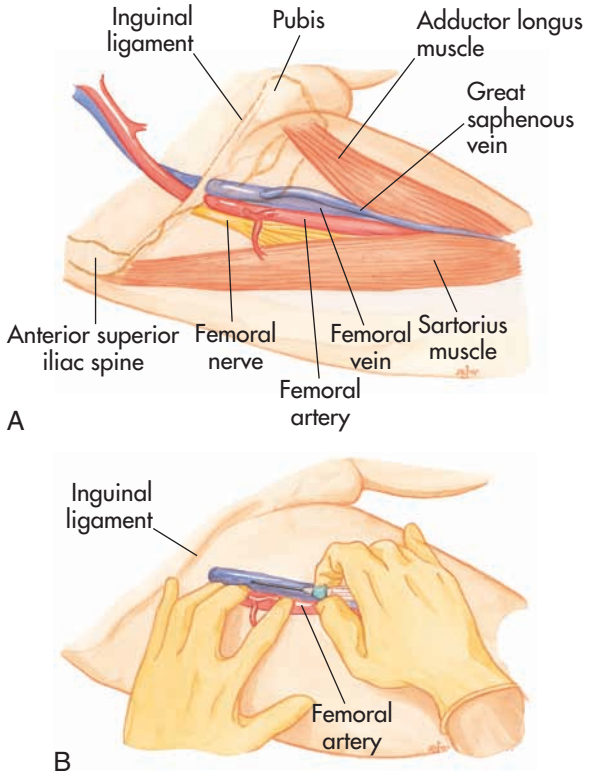

FIGURE 1 **A,** Anatomy of the femoral vein. **B,** Femoral venipuncture.

NOTE

Central line placement is not routinely performed in the prehospital setting. Complications include pneumothorax, arterial injury, and abnormal placement. Critical care paramedics and paramedics who transport critical patients will be exposed to central lines and should be familiar with these devices.

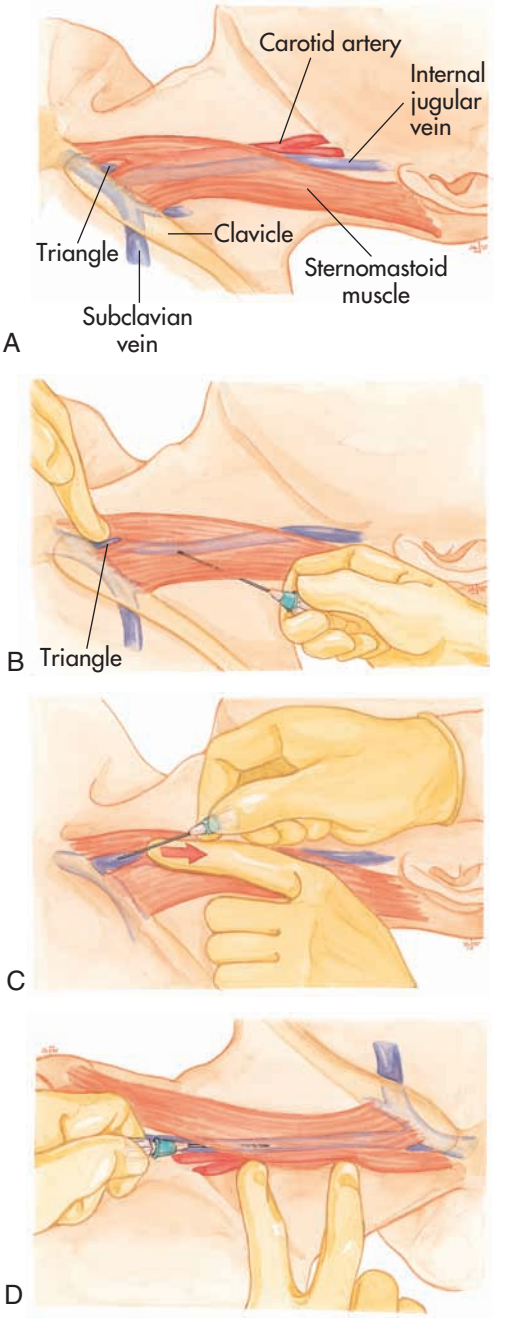

FIGURE 2 **A,** Anatomy of the internal jugular vein. **B,** Posterior approach for internal jugular venipuncture. **C,** Central approach for internal jugular venipuncture. **D,** Anterior approach for internal jugular venipuncture.

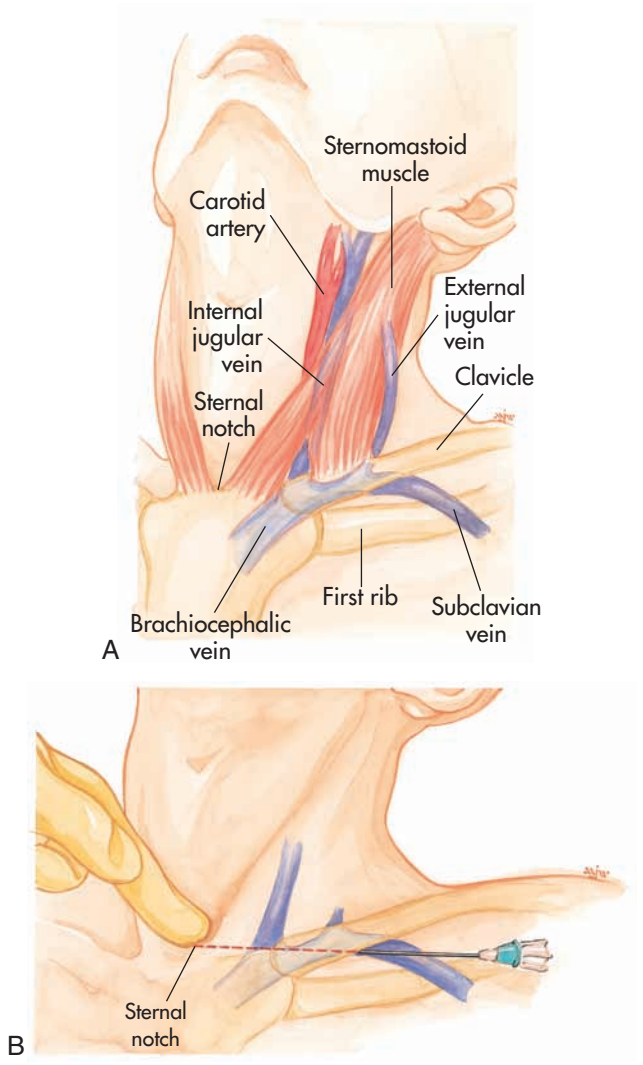

FIGURE 3 **A,** Anatomy of the subclavian vein. **B,** Infraclavicular subclavian venipuncture.

Complications Specific to Central Venous Cannulation

Cannulation of the central veins presents specific dangers. These are in addition to the complications common to all intravenous techniques. The paramedic must be alert to these dangers because they can be fatal if unrecognized. It is essential when caring for a patient with a central vein catheter to eliminate all air from the tubing to reduce the risk of air embolism.

COMPLICATIONS OF INTERNAL JUGULAR AND SUBCLAVIAN VEIN CANNULATION

Local Complications

- Hematoma may occur, either from the vein itself or from an adjacent artery.
- Damage may occur to an adjacent artery, nerve, or lymphatic duct. Inadvertent puncture of the carotid artery is not uncommon when jugular vein cannulation is attempted. If a hematoma occurs on one side of the neck, it is hazardous to attempt puncture on the opposite side. This could result in bilateral hematomas that severely compromise the airway.

Systemic Complications

- Pneumothorax is common.
- Hemothorax can occur.
- Air embolism can occur.
- Fluid may infiltrate into the mediastinum or the pleural cavity from an extruded catheter.

COMPLICATIONS OF FEMORAL VEIN CANNULATION

Local Complications

- Hematoma may occur, either from the vein itself or from the adjacent femoral artery.
- Thrombosis may extend to the deep veins and lead to edema of the leg.
- Phlebitis may extend to the deep veins.
- Use of the femoral vein frequently precludes subsequent use of the saphenous vein.
- Inadvertent arterial puncture may lead to excessive bleeding (including retroperitoneal bleeding) and can also lead to delayed aneurysm or pseudoaneurysm formation.

Systemic Complications

- Thrombosis or phlebitis may occur and extend to the iliac veins or even the inferior vena cava.

ACCESSING THE UMBILICAL VEIN

As described in Chapter 46, the umbilical cord contains three vessels: two arteries and one vein. The vein in the umbilical cord has a thin wall and is larger than the arteries. The arteries are thick walled and usually paired. To gain access to the umbilical vein, the paramedic should take the following steps (Figure 4):

1. Set up intravenous (IV) fluid (per protocol) and tubing with a three-way stopcock.
2. Select a 3.5 or 5 French umbilical catheter.
3. Connect the catheter to the stopcock and fill the catheter with IV fluid, which will remove any air.
4. Cleanse the umbilical stump and surrounding skin with antibacterial solution (per protocol).
5. Loosely tie umbilical tape around the cord near the body so that pressure can be applied to control bleeding.
6. Hold the umbilical stump firmly and trim (with a scalpel) the cord several centimeters above the abdomen.
7. Locate the umbilical vein and insert the catheter until blood is freely obtained. Do not insert the catheter more than 6 to 8 cm (2-3 inches). If the catheter is inserted farther, there is a risk of infusing solutions directly into the liver rather than the systemic circulation. Take care to avoid introduction of air emboli into the umbilical vein.
8. Draw blood for a sample, if needed.

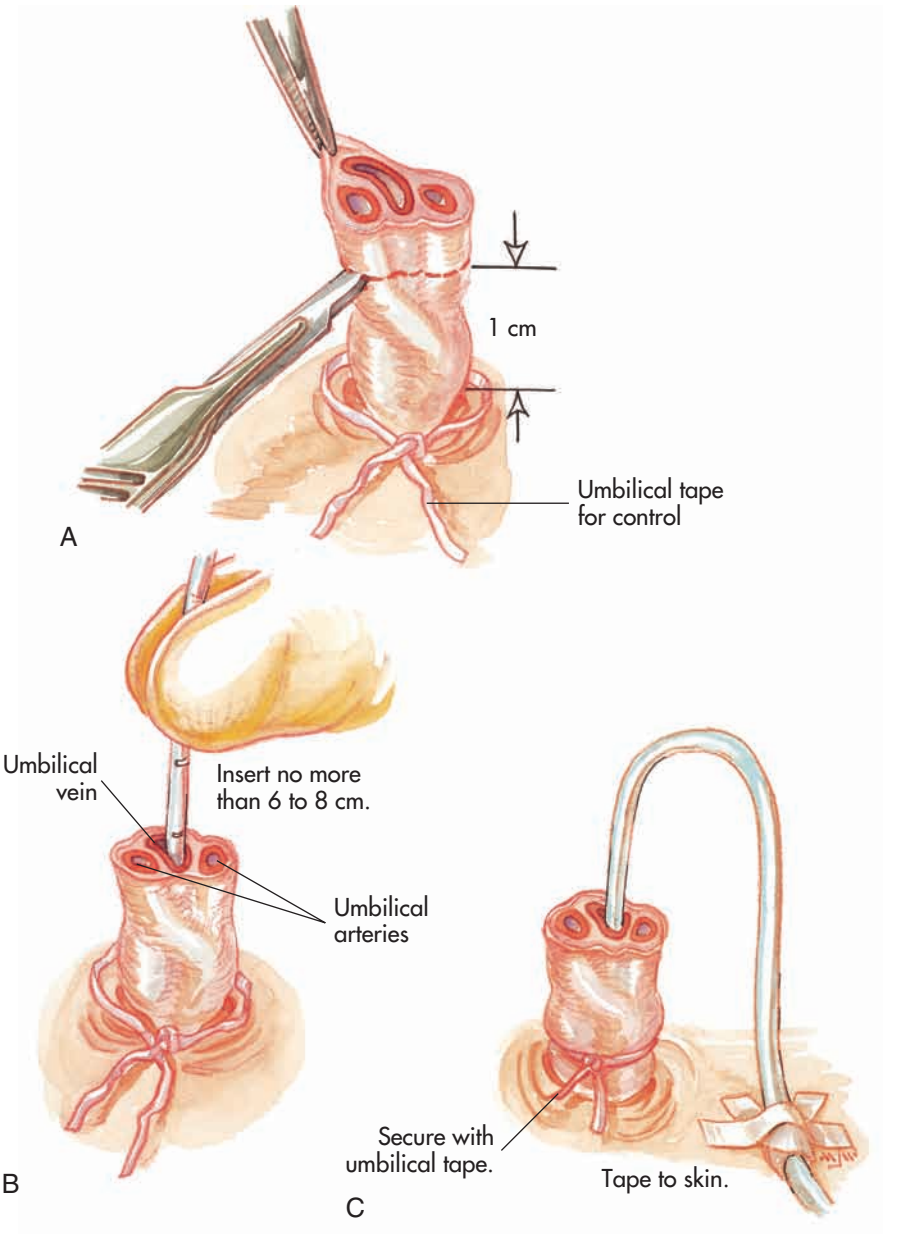

FIGURE 4 Umbilical vein cannulation procedure. **A,** Identify the umbilical vein after trimming the cord. **B,** Insert the umbilical catheter into the vein. **C,** Secure the base of the cord to hold the catheter in place and stabilize the catheter with tape.

9. Initiate the infusion and regulate the fluid flow per medical direction.
10. Secure the catheter in place with tape and cover with a sterile dressing.
11. Document the procedure.

The umbilical cord also may be cannulated by using a typical IV catheter. Insert the catheter-over-needle through the side of the proximal end of the cord into the vein and advance it upward through the translucent wall. Start the infusion, adjust the fluid flow per medical direction, and secure the catheter in place with tape.

ARTERIAL BLOOD GAS (ABG) SAMPLING

Arterial blood gas (ABG) measurements refer to the analyses of arterial blood to determine the pH (the negative log of the hydrogen ion concentration), the partial pressure of carbon dioxide, the partial pressure of oxygen, and the hemoglobin saturation of arterial blood. Pulse oximetry has made ABG measurement much less common. However, it is useful for measuring carbon dioxide and helps identify abnormal hemoglobin states such as carboxyhemoglobin

and methemoglobin, although these can also be determined through venous blood gas analysis. The measurements often are used along with pulmonary function tests. The results of ABG sampling provide information about the diffusion of gas across the alveolar-capillary membrane. It also provides a measurement of the adequacy of tissue oxygenation. Patients with acid-base disturbances may require repeated ABG analysis to determine acid-base status and the adequacy of ventilation and oxygenation. The ABG sample that is tested should be less than 1 hour old.

LOOK AGAIN
See Chapter 11: General Principles of Pathophysiology, pp. 227-232.

Obtaining the ABG Sample

ABGs usually are drawn from the radial or femoral artery (or from an indwelling arterial catheter).To obtain an ABG sample, the paramedic should take the following steps:

Arterial Puncture of the Radial Artery

1. Collect the following equipment: (Commercial ABG kits are available)
   a. Heparinized 3-mL syringe
   b. 23-gauge or 25-gauge needle with safety guard
   c. Crushed ice for arterial blood sample
   d. Antiseptic wipes
   e. 2 × 2 gauze
   f. Air lock or cap for syringe
   g. Disposable gloves
   h. Tape
2. Verify the patient's name and explain the procedure.
3. Palpate the radial artery.
4. Perform Allen's Test (Figure 5)
   a. Have the patient make a tight fist
   b. Apply direct pressure to the radial and ulnar arteries
   c. Have the patient open fisted hand
   d. Release pressure over the ulnar artery; observe color of fingers, thumbs, and hands. If flushing occurs within 15 seconds, the test is positive and the puncture can proceed. If flushing does not occur within 15 seconds, the test is negative and the radial artery in that wrist should be avoided. Check opposite wrist.
5. Hyperextend the patient's wrist over a rolled towel.
6. Wash hands and don disposable gloves.
7. Cleanse the site in a circular motion with approved antiseptic wipes.
8. Flush heparin from the syringe, leaving heparin in the needle and hub.
9. While palpating the radial artery, insert the needle at a 45-degree angle while stabilizing the artery with your free hand (Figure 6).
10. Observe for pulsating blood into the syringe, indicating arterial puncture.
11. Withdraw 2 mL of blood.
12. Remove the needle and syringe from the artery and have a co-worker apply direct pressure to the puncture site with 2 × 2 gauze for approximately 3 to 5 minutes. Skin should remain warm, pink, and with good capillary refill (Figure 7). Reevaluate the puncture site for continued bleeding or hematoma formation. Assess arterial flow above and below the puncture site.
13. Expel any air and cap syringe. Rotate the syringe so that blood mixes with heparin to prevent clotting.
14. Place the syringe in crushed ice.
15. Label the specimen with the patient's name, body temperature, and the amount of inspired oxygen (if the patient is on oxygen therapy).
16. Immediately send the specimen to the laboratory (per policy).
17. Document and record the procedure in the patient care report.

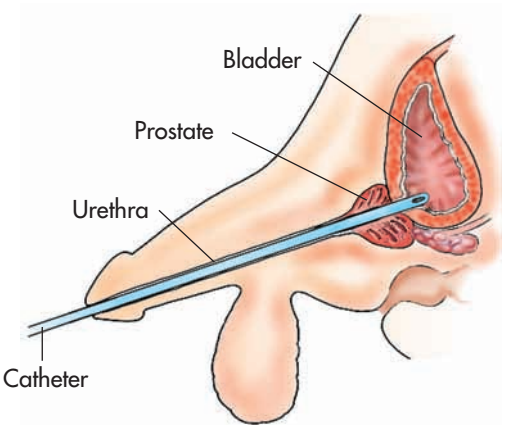

FIGURE 8 Male bladder catheterization.

BOX 1 Necessary Equipment for Bladder Catheterization

- Personal protective equipment
- Urinary catheterization set containing the following:
  - Sterile gloves
  - Antiseptic solution
  - Sterile cleansing sponges
  - Sterile drapes or towels
  - Syringe containing 5 mL sterile water
  - Connecting tubing and collection bag
  - Water-soluble sterile lubricant
- Urinary catheter with 5-mL Foley balloon
  - Catheter usually is a 16 Foley for males and a 14 Foley for females.
  - Standard length is 18 inches.

BLADDER CATHETERIZATION

As described in Chapter 52, bladder catheterization using a Foley catheter may be indicated to empty the bladder of a patient with urinary retention, to replace an indwelling urinary catheter that is not functioning, or to measure urine output in critical patients. Bladder catheterization is an invasive procedure. It carries some associated risks. These include the introduction of bacteria, which may lead to urinary tract infection, hematuria, and the creation of a false urethral passage, which may result in significant blood loss and the need for surgical repair.

Indwelling Foley Catheter Insertion

To insert a Foley catheter, the paramedic should prepare the required equipment (e.g., Foley catheter insertion set). The recommendations of the manufacturer should be closely followed (Box 1). Most patients will be anxious and frightened of the procedure. The paramedic should provide a full explanation of the procedure, reassure the patient, and make every effort to ensure privacy.

MALE CATHETERIZATION (FIGURE 8)

1. Explain the procedure to the patient.
2. Wash hands.
3. Place the patient in the supine position and remove the patient's pants and undergarments.
4. Wash hands.
5. Open the catheterization set using sterile technique.
6. Wash hands and don sterile gloves.
7. Place one sterile drape under the patient's penis and another above the penis to cover the abdomen.
8. Open a package of antiseptic solution and saturate sterile sponges (or cotton balls).
9. Attach the syringe to the catheter and test the balloon to make sure it inflates.
10. Open a package of water-soluble lubricant and lubricate the first several inches of the catheter.
11. Grasp the patient's penis with one hand and retract the foreskin (if present).
12. With the other hand, cleanse the glans with a sterile sponge (maintaining hand sterility) and then discard the sponge. Repeat the procedure.
13. Raise the shaft of the penis upright to straighten the penile urethra and pass the tip of the catheter through the meatus.
14. Continue passing the catheter with gentle, steady pressure, advancing the catheter 7 to 9 inches or until urine flows out the distal end of the catheter. Once urine appears, advance the catheter another 2 inches. If mild resistance is felt at the external sphincter, slightly increase traction on the penis and continue with steady, gentle pressure on the catheter. *If significant resistance is met, withdraw the catheter and consult with medical direction.*
15. Attach the syringe to the catheter and inflate the balloon with 3 to 5 mL of sterile saline.

16. Gently pull back on the catheter until the balloon rests against the prostatic urethra. (Resistance will be encountered.) Reposition the retracted foreskin of an uncircumcised patient. Attach the drainage bag to the catheter.
17. Run the catheter tubing along the patient's leg and tape the connecting tubing to the patient's thigh. Do not place any tension on the catheter.
18. Attach the collection bag to the bed or stretcher at a level below that of the patient to facilitate drainage by gravity.

FEMALE CATHETERIZATION (FIGURE 9)

1. Prepare the patient and equipment as described in steps 1 to 4 and 6 to 8 of the previous procedure. Female patients should be positioned with knees bent, hips flexed, and feet resting about 24 inches apart. The patient should be draped appropriately by placing one sterile drape just under the patient's buttocks; position the fenestrated drape over the perineum, exposing the labia.
2. With one hand, separate the patient's labia to expose the urethral meatus.
3. Cleanse the surrounding area with a sterile sponge or cotton ball (maintaining hand sterility) in downward strokes from anterior to posterior. Discard the sponge. Repeat the procedure.
4. Introduce the tip of the well-lubricated catheter into the urethra using aseptic technique. Continue to advance the catheter 2 to 3 inches with gentle, steady pressure until urine flows out of the distal end of the catheter. Once urine appears, advance the catheter another 2 inches.
5. Attach a syringe to the catheter. Inflate the balloon with 3 to 5 mL of sterile saline.
6. Gently pull on the catheter until resistance is encountered.

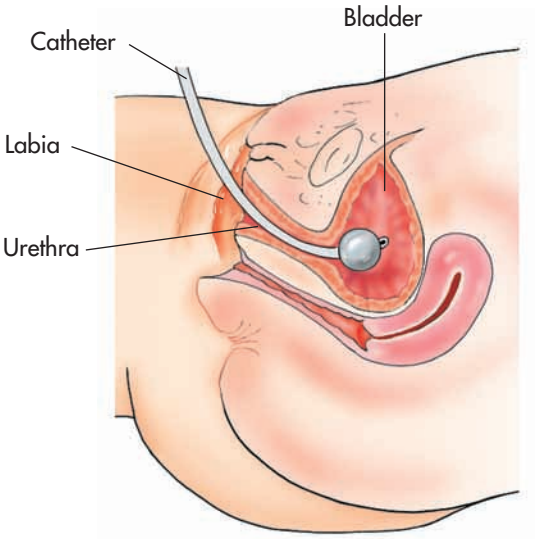

FIGURE 9 Female bladder catheterization.

7. Attach the collection tubing and bag to the catheter and secure the collection tubing to the patient's thigh as described above in steps 14 and 16 of the previous procedure. Position the collection bag to facilitate drainage.

INVASIVE HEMODYNAMIC MONITORING

Invasive hemodynamic monitoring is the measurement and interpretation of hemodynamic parameters. It requires placement of a catheter (central venous line, arterial line) in a vein, artery, or heart chamber. Knowledgeable health care personnel can obtain and interpret many different pieces of information from this tool, depending on the type of catheter used. Box 2 lists possible complications and risks associated with hemodynamic monitoring.

Hemodynamic monitoring is most useful for assessing and managing patients with hypertensive emergencies, shock, pulmonary edema, sepsis, and multiple organ failure. In particular, a pulmonary artery (PA) catheter can help distinguish among the various types of shock (cardiogenic, hypovolemic, obstructive, and distributive). Hemodynamic monitoring requires special equipment to produce visible waveforms on an oscilloscope and pressure monitor (Figure 10 and Box 3). These waveforms reflect the phases of the cardiac cycle and can be used to monitor systemic arterial pressure, right atrial pressure (central venous pressure), left atrial pressure, and pulmonary artery pressure (Figure 11).

Systemic Arterial Pressure Monitoring

Systemic arterial pressure monitoring is designed to measure systemic pressure as close to the heart as possible. This monitoring often implies continuous arterial pressure monitoring through the use of an arterial line. The placement of an arterial line in a peripheral artery allows for continuous and accurate measurement of arterial pressure. It may be indicated for monitoring drug therapy (e.g., titration of vasopressors, inotropics), blood pressure, or for frequent arterial blood gas sampling. Indwelling arterial catheters may be inserted into the radial, femoral, brachial,

BOX 2 Possible Complications and Risks Associated with Hemodynamic Monitoring

- Air embolism
- Arterial spasm
- Bleeding
- Dysrhythmias (with heart chamber catheterization)
- Hematoma
- Pneumothorax (with some insertion sites)
- Systemic infection
- Thrombosis
- Tissue and blood vessel injury

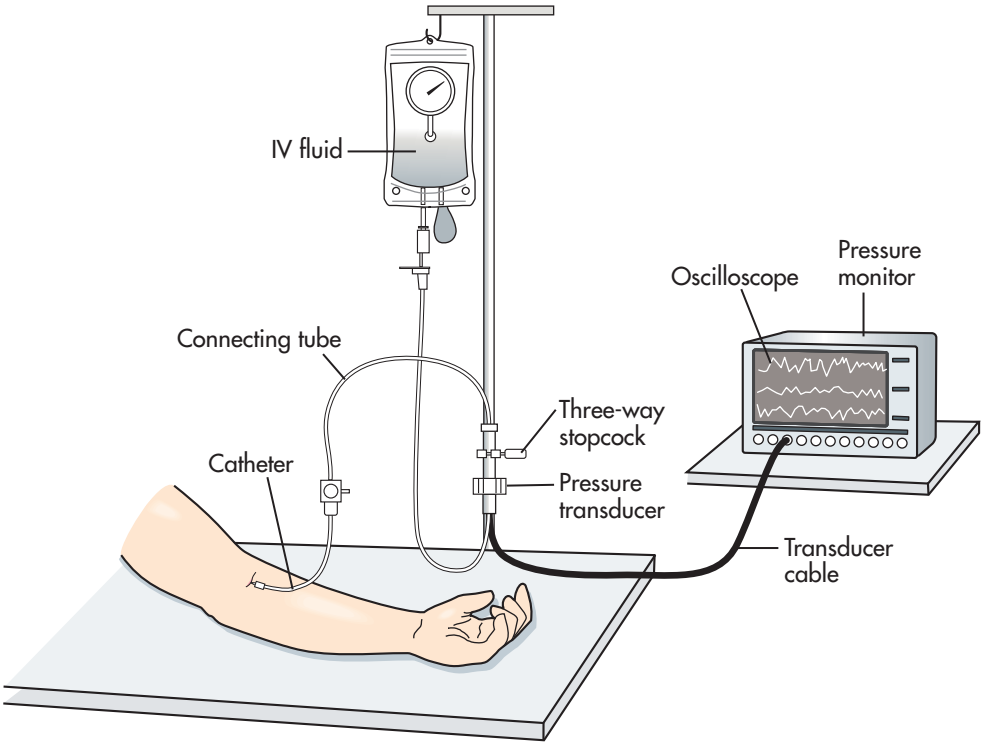

FIGURE 10 Hemodynamic monitoring equipment.

BOX 3 Troubleshooting Monitors

Most monitors used in patient care have a variety of alarms to alert a malfunction. A systematic method of troubleshooting the alarms is to begin with the patient first. Then, look at the equipment:

1. Check the patient.
2. Check the insertion site.
3. Check the tubing or lead wire.
4. Check connections to the monitor.
5. Check the monitor.
6. Check the electrical connection or power source.

or dorsalis pedis artery. The radial or brachial artery is most commonly used for continuous pressure monitoring.

Right Atrial Pressure (RAP) Monitoring

Right atrial pressure monitoring may be used to assess right ventricular preload in critically ill patients. RAP monitoring (also known as *central venous pressure [CVP] monitoring*) allows direct measurement of pressure in the right atrium and *reflects* right ventricular pressure. It is used to monitor blood volume, right ventricular function, and central venous return. The vascular access device also can be used to administer IV fluids, medications, blood, and to obtain blood samples. Although monitoring RAP measures the pressure in the right atrium, this is used to indirectly determine the volume of blood in the right atrium and thus the right ventricular preload. Common insertion sites for RAP monitoring are the internal jugular vein and the subclavian vein.

NOTE
RAP monitoring may reflect left ventricular preload but can be misleading, particularly in conditions in which there is right atrial or right ventricular dysfunction.

Left Atrial Pressure (LAP) Monitoring

Left atrial pressure monitoring measures the pressure of the blood as it returns to the left side of the heart. It is normally measured indirectly by measuring the pulmonary capillary wedge pressure described later. LAP is a reliable indicator of left ventricular end-diastolic pressure, and therefore, of left ventricular function. (This is true except in cases of severe mitral stenosis if LAP is obtained using PCWP.) Short-term LAP monitoring is usually performed in the operating room during cardiac surgery, when a catheter is placed directly into the left atrium. In most other settings, LAP more often is indirectly monitored through a pulmonary artery catheter.

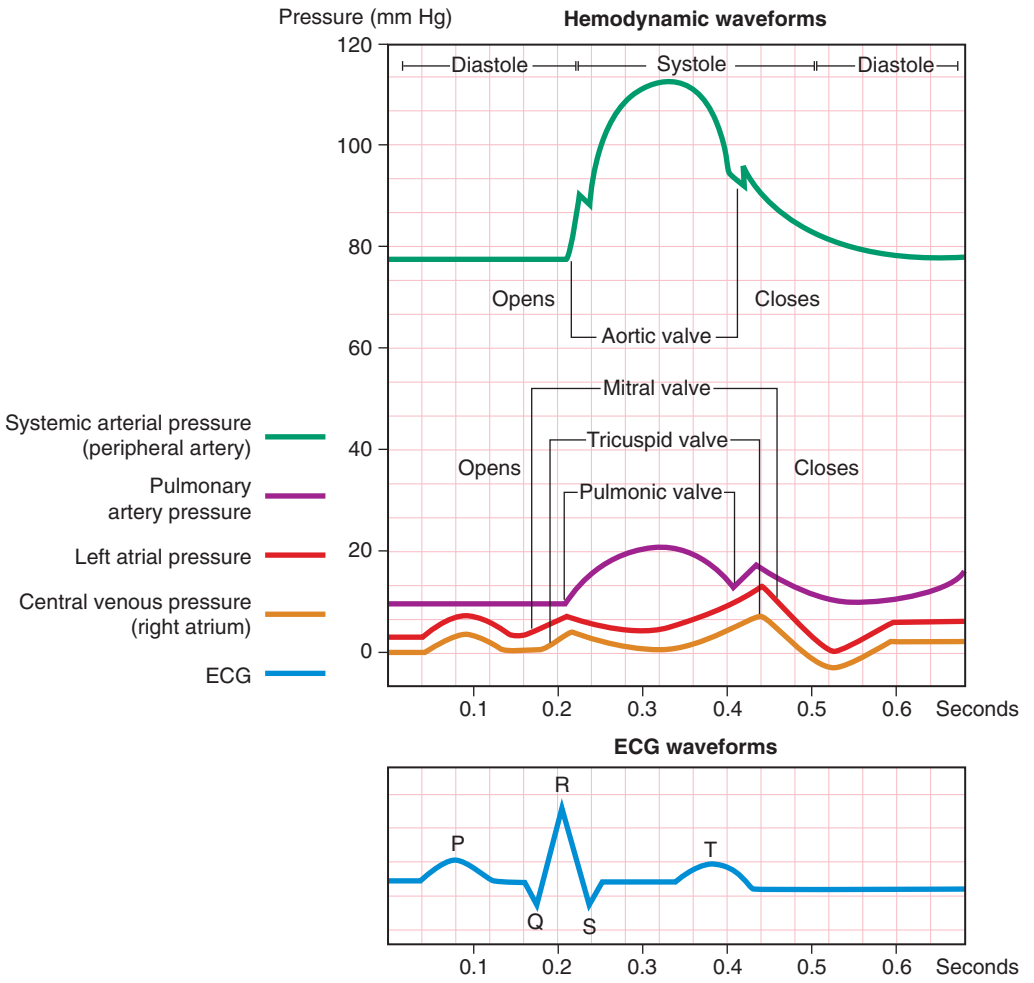

FIGURE 11 How hemodynamic waveforms reflect the cardiac cycle.

Pulmonary Artery Pressure (PAP) Monitoring

Pulmonary artery pressure monitoring provides an indirect measure of left ventricular function. The catheter used for PAP monitoring has four lumens (and sometimes a fifth proximal infusion port) that contain a balloon inflation port, proximal and distal injection ports, and a thermistor lumen for obtaining cardiac output measurements (Figure 12). Some PAP devices are also designed for transvenous pacing.

The catheter is usually inserted in the subclavian or internal jugular vein and is passed through the right atrium and right ventricle into the pulmonary artery. PAP monitoring is useful in treating shock, congestive heart failure (CHF), pulmonary edema, pulmonary embolism, and for monitoring patients who are undergoing cardiac surgery. The PAP reflects venous pressure in the lungs, the mean filling pressure for the left side of the heart, and indicates left ventricular end-diastolic pressure (in the absence of mitral valve disease). In addition to measuring pulmonary artery pressure, PAP monitoring provides a measurement

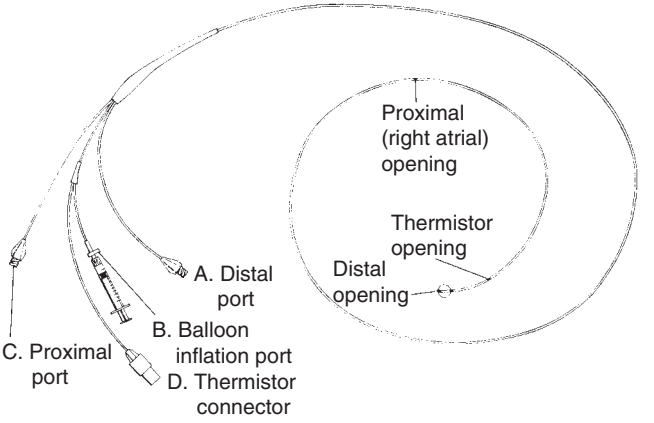

FIGURE 12 Number 7 French quadruple lumen, thermodilution pulmonary artery catheter. (Darovic GO: *Hemodynamic monitoring, invasive and noninvasive clinical application,* ed 3, Philadelphia, 2003, Saunders.)

of RAP during insertion, pulmonary capillary wedge pressure (PCWP), cardiac output, and mixed venous oxygen saturation.

PULMONARY CAPILLARY WEDGE PRESSURE

Pulmonary capillary wedge pressure (PCWP) (also known as *pulmonary artery wedge pressure [PAWP]*) helps to determine left ventricular function. It is measured when the pulmonary balloon of the PA catheter is inflated and occludes a pulmonary artery branch, allowing the distal lumen in front of the balloon to register left heart pressure. Once the measurement is obtained, the balloon is deflated and the catheter will float back into the pulmonary artery. (The balloon is only inflated for PCWP readings; it remains deflated for continuous PAP monitoring and during patient transports.) PCWP usually is measured every 4 hours.

CARDIAC OUTPUT

The **thermistor lumen** is a multilumen catheter device that measures cardiac output (CO) through a special computer. It does this by measuring the temperature of fluid in the body. It also aids in assessing left ventricular function and the function of heart valves. This measure is taken (as needed) by injecting a solution called *injectate* at a known temperature (iced or room temperature) into the proximal lumen port of the PA catheter or through a closed injectate delivery system. The solution then mixes with blood from the superior vena cava or the right atrium (depending on the location of the catheter), and lowers the temperature of the heart's blood. The thermistor detects the drop in temperature. The temperature change is analyzed by the computer, calculating cardiac output of the right and left ventricle. Continuous CO measurements can also be obtained by special catheters and equipment that change the temperature of the heart's blood at specific intervals without injectate, calculating CO over several minutes.

MIXED VENOUS OXYGEN SATURATION

Mixed venous oxygen saturation (SVO_2) is the direct measurement of the blended venous blood (from the inferior and superior vena cavae) usually sampled from the right atrium or ventricle. It reflects the balance between oxygen delivery and consumption in the tissues and can serve as an early indicator of low cardiac output. SVO_2 can be measured from a PA catheter when mixed venous blood from organs and tissues flows back to the lungs. This measurement can be taken intermittently by withdrawing blood from the port of a PA catheter, or continuously by using fiberoptic catheters and an oximetry system that assesses cardiac and pulmonary function.

INTRAAORTIC BALLOON PUMP

An **intraaortic balloon pump** (IABP) is a mechanical cardiac assist device that benefits patients with actual or potentially life-threatening circulatory problems. Indications for its use include patients:

- In cardiogenic shock as a bridge to reperfusion therapy
- With ventricular septal defect and acute mitral regurgitation
- Who are candidates for cardiac transplant
- Who are high-risk surgical patients
- Who are high risk and undergoing angiography or angioplasty
- Who have refractory ventricular dysrhythmias complicating AMI
- Who have recurrent postinfarction angina

The catheter with balloon usually is inserted in the patient's femoral artery and is advanced until the catheter lies in the aorta, just beyond the left subclavian artery. The balloon is at the distal end of the catheter, and when inflated by a computerized pump, it fills the patient's descending thoracic aorta. The balloon inflates during diastole, causing blood in the aorta to be forced back proximally into the coronary arteries, thus increasing coronary artery flow. This allows for increased perfusion of the myocardium, helping to relieve myocardial ischemia. Just before systole, the balloon deflates, causing a decrease of the pressure in the aorta, making it easier for the left ventricle to expel blood during contraction. This results in decreased workload for the left ventricle, and increases cardiac output and perfusion of vital organs. As a rule, the IABP is initially set to an inflation/deflation cycle for each cardiac cycle (1:1 ratio) and then is gradually reduced (2:1, 3:1 ratio), based on the patient's condition. Most IABP devices adapt the deflation automatically in the situation of ventricular ectopy or other dysrhythmias. If the timing is not correct, a number of physiologic changes can occur (Table 1) (Figure 13).

NOTE

Some manufacturers have adapters especially for transport in the event the transport team's pump is different than the one at the referring facility. These adapters allow interfacing between the different pumps.

TABLE 1 IABP Timing Errors

Timing Error	Effect
Early inflation	Premature closure of the aortic valve causing aortic regurgitation
Late inflation	Sub-optimal coronary perfusion
Early deflation	Retrograde coronary blood flow
Late deflation	Increases the resistance the balloon pumps against (afterload)

From ASTNA: *ASTNA patient transport: principles and practice,* ed 4, St Louis, 2009, Mosby.

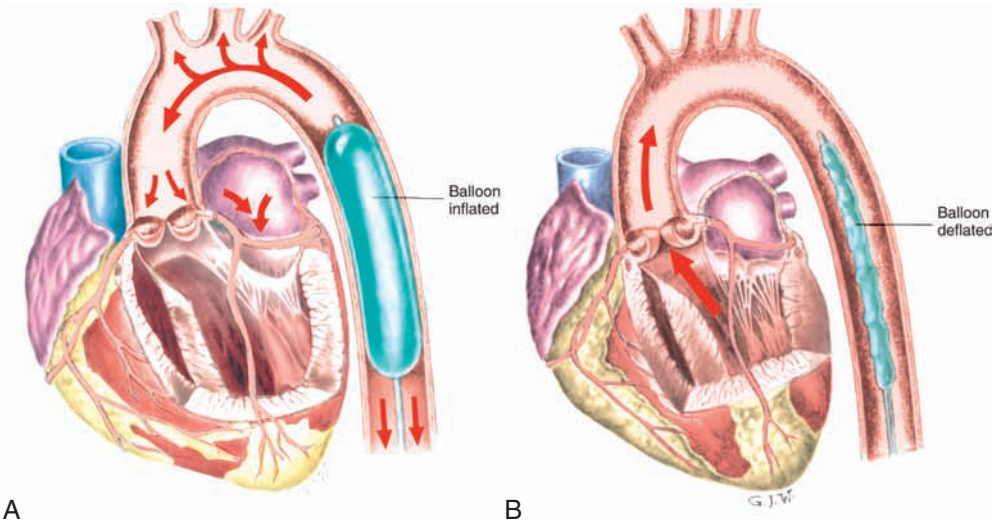

FIGURE 13 Mechanisms of action of the intraaortic balloon pump. **A**, Diastolic balloon inflation augments coronary blood flow. **B**, Systolic balloon deflation decreases afterload.

SHOW ME THE EVIDENCE

In this case series, researchers prospectively evaluated critical care paramedic transport of 29 patients transferred with IABP. Reports were evaluated to determine appropriateness of care and adverse events. During transport, there were 22 complications involving 11 patients. All were managed effectively by the paramedics. No life-threatening complications persisted, and no patient died during transfer. The authors conclude that specially trained paramedics can safely transfer IABP patients in their system.

From MacDonald R, Farquhar S: *Transfer of intra-aortic balloon pump-dependent patients by paramedics: a case-series*, 2009. Paper presented at the National Association of EMS Physicians, Naples, Fla. www.allacademic.com/one/www/www/index.php?cmd=www_search&offset=0&limit=5&multi_search_search_mode=publication&multi_search_publication_fulltext_mod=fulltext&textfield_submit=true&search_module=multi_search&search=Search&search_field=title_idx&fulltext_search=Transfer+of+intra-aortic+balloon+pump-dependent+patients+by+paramedics%3A++a+case-series.

INTRACRANIAL PRESSURE MONITORING

As described in Chapter 40, a rise in intracranial pressure (ICP) can decrease cerebral perfusion. ICP monitoring is often used in patients with brain lesions, head trauma with bleeding or edema, hydrocephalus, encephalitis, and those who have an overproduction and/or insufficient absorption of cerebrospinal fluid. ICP can be monitored using an intraventricular cannula (the most common method), an epidural catheter, a subdural or subarachnoid monitoring device, or by a fiberoptic transducer tipped probe (Figure 14). All devices must be placed by a physician, and all monitoring systems require calibration (Box 4).

LOOK AGAIN

See Chapter 40: Head, Face, and Neck Trauma, pp. 1166-1168.

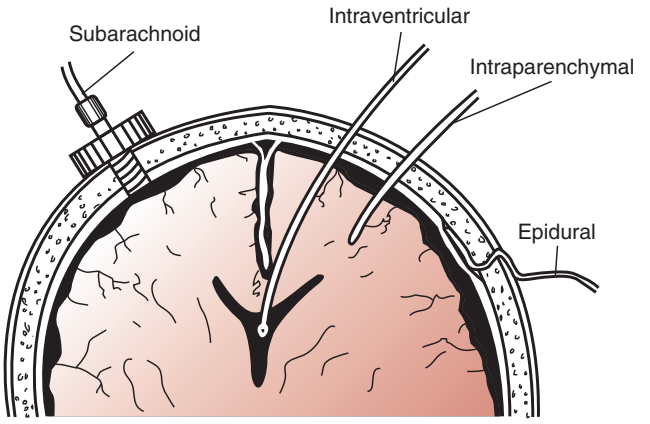

FIGURE 14 Intracranial pressure monitoring sites. (Kee JT: *Youman's neurological surgery*, ed 4, Philadelphia, 1996, Saunders.)

BOX 4 Important Considerations in ICP Monitoring

- Maintain sterile technique.
- Keep all stopcocks ports capped unless one must be opened to expel air or to balance the transducer.
- Expel all air from the tubing or stopcock ports before connecting the line to the patient.
- Never flush any fluid into the patient's cranial cavity. Doing so will raise ICP and invite infection.

ICP Waveforms

The normal range for ICP in an adult is 10 to 15 mm Hg or less, but this can vary by individual with position changes and activity level. For example, rotation of the head either to the right or left and head-down positions can increase ICP significantly in both normal patients as well as those

with head injury or stroke.[1] For patients with head trauma, it is generally agreed that moderate (15° to 45°) head elevation significantly reduces ICP, whereas head elevation >45° may be dangerous because of a critical decrease in cerebral perfusion pressure (CPP).[2] Therapies that may be needed to control increasing ICP include:

- Maintaining oxygenation to improve gas exchange
- Avoiding hypoxia and/or hypercapnia
- Positioning the patient by moderately elevating the patient's head or the head of the stretcher to optimize cerebral perfusion pressure (CPP) and to lower ICP
- Avoiding maneuvers that might increase intrathoracic or intraabdominal pressure (e.g., coughing, Valsalva maneuver, patient movement, hip flexion)
- Preventing sudden variation in systemic blood pressure
- Administering osmotic diuretics and/or steroids to reduce cerebral edema and inflammation
- Restricting IV fluid therapy
- Providing sedation to prevent agitation
- Maintaining normal body temperature
- Avoiding seizure activity

BLOOD ADMINISTRATION

As described in Chapters 11 and 32, blood replacement therapy may be indicated when caring for patients who have suffered acute blood loss and in some patients who have symptomatic anemia or other disorders. Blood products that commonly are administered to critical patients include packed red blood cells, fresh frozen plasma, and platelets. (Whole blood is not commonly available, but it is still used occasionally.) Because of the risk of transfusion reactions and the possible transmission of infectious disease, blood products should be given only when specifically indicated. Before administering a blood transfusion:

1. The patient and blood product must be identified by two health care professionals.
2. Blood containing RBCs must be compared to the patient's ABO group and Rh type.
3. The name and identification number on the patient's wrist band must be compared to the slip on the blood bag.
4. The expiration date and time on the blood product must be identified. The blood bag should be turned upside down to gently mix it and inspect its contents for color and consistency.
5. The label must remain attached to the blood product until the transfusion is complete.

Blood and blood products can be safely administered through a peripheral IV line, Portacath, and most central lines. Optimally, the tubing of the administration set should be connected directly to the access line and should not be piggy-backed into an existing IV line (which can increase the risk of contamination). Peripheral IV access must be sufficient to maintain an adequate flow rate for the transfusion. Straight-type blood administration sets contain a standard filter in the tubing and are adequate for the administration of most blood products (Figure 15). Y type blood/solution administration sets contain a standard filter in the tubing with a Y-tubing above the filter to permit a dual connection for a blood component (e.g., red blood cells) and saline.

FIGURE 15 Blood administration set primed with normal saline. (Perry AG, Potter PA, Elkin MA: *Nursing interventions and clinical skills*, ed 5, St. Louis, 2012, Mosby.)

FIGURE 16 **A,** Electronic infusion device. **B,** Ambulatory infusion pump. (Perry AG, Potter PA, Elkin MA: *Nursing interventions and clinical skills*, ed 5, St. Louis, 2012, Mosby.)

IV INFUSION PUMPS

IV infusion pumps maintain a more accurate flow rate when providing fluid and medication therapy than the more common gravity systems. Many IV infusion pumps are available, and all require familiarity with the operating instructions for the specific device (Figure 16). Most models can be operated by battery as well as electric current. They incorporate warnings and alarms of low or high occlusion

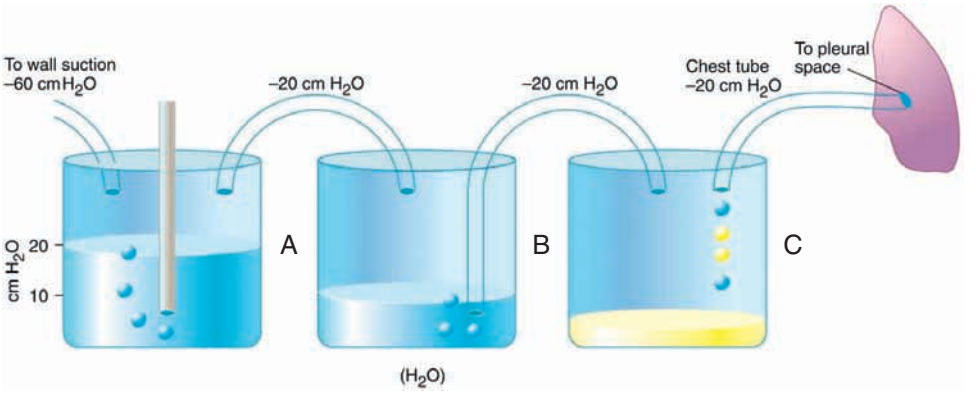

FIGURE 17 The standard three-bottle system is the basis for all commercial chest tube drainage systems. Pleural fluid and pleural air enter compartment C, which serves as a fluid collection trap so that the water-seal fluid volume will not rise (compartment B) and create resistance to air escaping the chest. Air cannot be inspired into the chest because of the water in compartment B. Open entrainment of room air through a submerged tube in compartment A buffers the amount of wall suction applied (−60 cm H_2O) to the height of the water column to standardize the pressure (−20 cm H_2O) transmitted to the chest. (Wilkins RL: *Egan's fundamentals of respiratory care*, ed 9, St Louis, 2009, Mosby.)

pressure, air in tubing, infusion complete, and low battery. All infusion pumps require frequent monitoring to ensure that they are accurately calibrated. During the infusion, a periodic assessment should include ensuring the flow rate corresponds to the rate displayed on the IV infusion pump, and that the infusion site is patent. If any problems occur during IV therapy, the paramedic should check all alarms (per the manufacturer's instructions), and stop the IV infusion if necessary.

TUBE THORACOSTOMY

As described in Chapter 42, chest wall injury can result in pneumothorax, hemothorax, or hemopneumothorax. These conditions can be life threatening and may need to be managed with pleural decompression. Pleural decompression can be achieved though needle thoracostomy (described in Chapter 42) or through tube thoracostomy.

LOOK AGAIN
See Chapter 42: Chest Trauma, pp. 1209-1212.

Tube thoracostomy involves the insertion of a catheter ("chest tube") through the chest wall into the pleural space. The tube is usually secured to the chest wall with sutures, and further secured with occlusive dressing and tape. It is then attached to suction to help with drainage. There are various chest wall drainage systems, but all work on the same principle as the original three-bottle system, described here for illustration (Figure 17). (Modern, rectangular plastic containers with three chambers have largely replaced the three-bottle system [Figure 18].) The first bottle collects the air, blood, or other fluid from the patient's pleural space through the chest tube. The second bottle or chamber is a

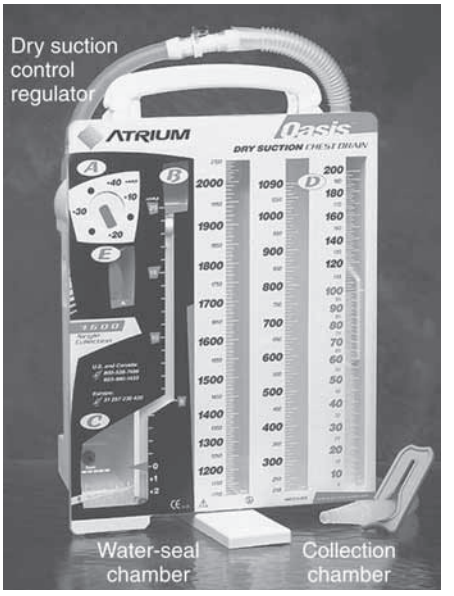

FIGURE 18 Chest tube drainage systems have three chambers: (1) collection chamber, (2) water-seal chamber, and (3) suction control chamber. Suction control chamber requires a connection to a wall suction source that is dialed up higher than the prescribed suction for the suction to work. (ENA: *Sheehy's emergency nursing: principles and practice,* ed 6, St Louis, 2010, Mosby.)

water seal bottle with a one-way valve that prevents air or fluid from moving backward into the first bottle. The third bottle contains water and is connected to suction. It controls the amount of suction either by a control valve or through a tube below the water surface. The higher the water level in the third bottle, the stronger the suction. (Some systems are waterless and contain a mechanical valve instead of water that allows drainage of blood or air.) The chest tube remains in place until all or most of the

air or fluid has been drained from the pleural space (usually a few days). Tube thoracostomy also is helpful in collecting infected fluid (e.g., pus) that has accumulated in the pleural space from bacterial infection or tuberculosis. Components and management of chest drainage systems are outlined in Box 5.

Care Considerations

After a chest tube is inserted, all tubing connections should be taped to minimize the risk of disconnection. Occlusive Vaseline gauze often is placed at the insertion site to minimize the risk of air leak. The chest drainage unit should be kept below the level of the chest when moving the patient, and the water seal units should always be maintained in an upright position. Tubing must be monitored for accidental kinking. Initial chest tube drainage that is more than 1500 mL should be reported. During transport all equipment should be assessed for air leaks and tube patency. Air leaks may be related to the chest drainage system, the injury to the lung, esophageal or bronchial injury, or a chest tube that is improperly placed. Persistent air leaks should be suspected if constant bubbling in the water seal chamber is observed (Box 6).

NOTE

If tube drainage stops suddenly, it is possible a clot has formed. If this occurs, the tube should be squeezed gently from its proximal to its distal end. Avoid clamping the chest tube during transport. With some injuries, this could lead to a tension pneumothorax. In some cases in which there is minimal drainage from the chest tube, a one-way valve may be attached to the tube during transport.[5]

BOX 5 Chest Drainage Systems: Components and Management[3,4]

Fluid Collection Chamber

Fluid drains from the patient through a long tube to a collection chamber, marked for assessment of drainage.

Water Seal Chamber

Allows air to pass out, via bubbles, through the bottom of the chamber. Often calibrated for measuring intrathoracic pressure and may have float valve to protect patient from high negativity. With the water seal chamber, during spontaneous respirations, the water level should rise during inhalation and fall during exhalation. This oscillation is called *tidaling* and is one indicator of a patent pleural chest tube.

Suction Control Chamber

Improves drainage and helps overcome the air leak. Keep suction control at –10 to –20 cm H_2O. Dry suction control systems provide many advantages: higher suction pressure levels can be achieved, set-up is easy, no continuous bubbling provides for quiet operation, and there is no fluid to evaporate, which would decrease the amount of suction applied to the patient. Instead of regulating the level of suction with a column of water, the dry suction units are controlled by a self-compensating regulator. Suction can be set at –10, –15, –20, –30, or –40 cm H_2O. The unit is preset at –20 cm H_2O when opened. Patient situations that may require higher suction pressures of –30 or –40 cm H_2O include a large air leak from the lung surface, empyema, a reduction in pulmonary compliance, or anticipated difficulty in expansion of the pulmonary tissue.

Nursing Responsibilities

Secure all connections. Monitor catheters to prevent kinking. Monitor drainage output. Assess for air leaks. Maintain unit in upright position.

Assessing for Air Leaks

Look at the underwater seal. Leaks may originate with the patient or the drainage system. (Check the patient history. Would you expect a patient air leak?). For a patient receiving mechanical ventilation with positive end-expiratory pressure (PEEP), leaking causes continuous bubbling. Note the pattern of the bubbling. If it fluctuates with respirations (i.e., occurs on exhalation in a patient breathing spontaneously), the most likely source is the lung. Momentarily clamp the chest tube at the dressing site with a toothless/padded clamp. Move the clamp incrementally toward the drainage unit—when you place the clamp between the source of the air leak, and the water seal/air leak meter chamber, the bubbling will stop. If bubbling stops the first time you clamp, the air leak must be at the chest tube insertion site or the lung. If bubbling continues, the leak is distal to the clamp. If bubbling stops before the end of the tubing, the leak is in the tube, so it must be replaced. If the unit is still bubbling when the very end of the tubing is clamped, the unit has the leak and should be changed. If the leak is at the insertion site, remove the chest tube dressing and inspect the site. Make sure the catheter eyelets have not pulled out beyond the chest wall. Replace the dressing. Notify the physician of any new, increased, or unexpected air leaks that are not corrected by the above actions.

Indications of Patency

The water level in the water seal should fluctuate with breathing, rising with inspiration and falling with expiration, and is an indicator of chest tube patency. If the patient is on mechanical ventilation, this pattern is reversed because breaths are delivered under positive pressure. Fluctuations stop when the lung is fully reexpanded or when the tube is kinked or compressed.

Milking/Stripping the Tube

Vigorous milking or stripping can create dangerously high negative pressures, placing the patient at risk for mediastinal trauma. Use extreme caution, and follow your hospital policy.

To Clamp or Not to Clamp?

Never clamp a chest tube during patient transport unless the chest drainage system becomes disrupted during patient movement, and then only if there is no air leak.

From Emergency Nurses Association: *Sheehy's emergency nursing: principles and practice,* ed 6, St Louis, 2009, Mosby.

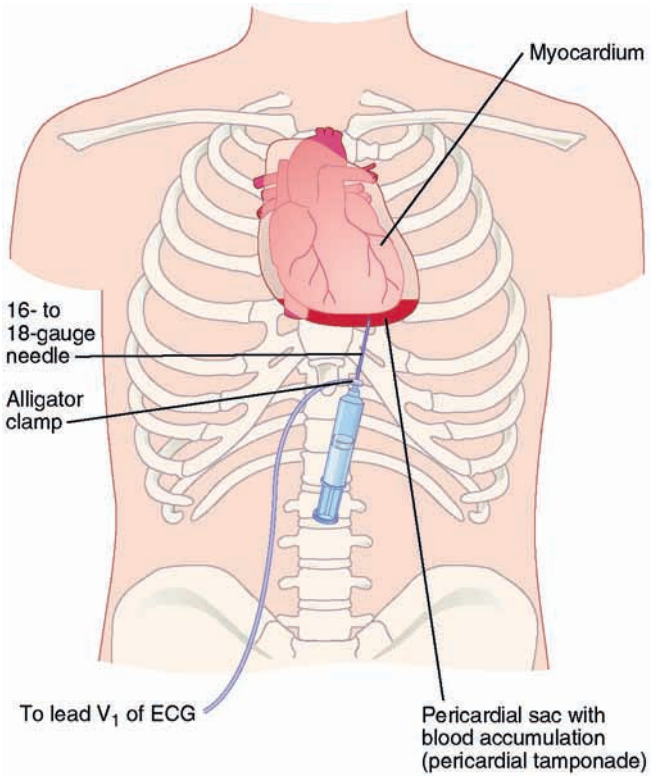

FIGURE 19 Pericardiocentesis (Holleran RS: *Air and surface patient transport: principles and practice,* ed 3, St Louis, 2010, Mosby.)

BOX 6 Checking for Air Leaks in a Chest Drainage System

1. Occlude the chest or drainage tube intermittently along the length of the system.
2. Reinforce the chest dressing and all connections.
3. If the bubbling stops when you occlude the tubing close to the drainage unit, consider replacing the unit if possible.

PERICARDIOCENTESIS

Pericardiocentesis is an invasive procedure in which a needle is inserted in the pericardial sac to aspirate blood or fluid. The primary indication for pericardiocentesis is pericardial tamponade. Pericardiocentesis carries significant risk, including penetration through the surface of the heart. Other complications include laceration of a coronary artery, laceration of the lung or liver, cardiac dysrhythmias, and increased tamponade. Ultrasound-guided pericardiocentesis is commonly used today and is deemed to reduce the rate of complications. The procedure for pericardiocentesis that is not guided by ultrasound is as follows (Figure 19):

1. Using aseptic technique, insert a 3-inch, 16- or 18-gauge needle (attached to a 50-cc syringe) at the angle of the xiphoid cartilage and the seventh rib.
2. Advance the needle at a 45-degree angle to the skin toward the right or left midclavicular line while aspirating the syringe with negative pressure. If the needle is advanced too far, a pulsation will be felt through the needle and syringe.
3. Aspirate as much fluid as possible. Fluid is usually encountered at a depth of 3 to 4 cm.(Removal of as little as 20 to 25 mL of blood from a distended pericardium may produce a dramatic blood pressure response.)
4. After withdrawing blood from the pericardia sac, attach a surgical clamp to the needle at the level of the skin to avoid accidental advancement of the needle.
5. If tamponade recurs, aspirate blood again if necessary.

SECTION TWO
Special Transport Considerations in Critical Care

Transporting patients with critical care needs can present special challenges for the paramedic. Most of the challenges are related to the unique equipment required for their care– equipment that is often unfamiliar to the EMS crew. Specific considerations that are discussed in this section are management of IV drug drips, transport ventilators, and extracorporeal membrane oxygenation (ECMO) support.

NOTE
Technical mishaps that are common in critical care transport include accidental extubation, ventilator disconnect, ECG monitor power failure, vasoactive drug interruption, and intravenous infiltration or disconnection.

DID YOU KNOW?
Flight Paramedics
Flight paramedics have played an important role in critical care transport since the 1970s. In 1986, these specialty care professionals united to form the National Flight Paramedic Association (NFPA). (The NFPA is now known as the International Association of Flight Paramedics [IAFP]). The NFPA prompted quality within the industry by serving as a founding member of the Commission on Accreditation of Air Medical Services (CAAMS) in 1990, now known as the Commission on Accreditation of Medical Transport Systems (CAMTS). Flight paramedics have special training and certification in critical care procedures and flight physiology (Certified Flight Paramedic [FP-C]). Today there are more than 1500 certified flight paramedics worldwide. (Figure 20). Air medical transport is further described in Chapter 53.

MANAGING IV DRUG DRIPS

There are a number of IV drugs that are administered via continuous infusion to critical care patients. Common drugs include ***amiodarone***, ***diltiazem***, ***dobutamine***, ***dopamine***,

FIGURE 20 Flight paramedic.

fentanyl, ***furosemide***, ***midazolam***, ***norepinephrine***, ***vasopressin***, and others. (See the Emergency Drug Index.) When preparing to transport a patient who is receiving an IV infusion of a drug that is unfamiliar to the paramedic, the paramedic should:

1. Consult with the physician or nurse caring for the patient before transport.
2. Ensure that the prescribed drip rate is documented and clearly understood.
3. Ensure personal comfort with workings of the infusion equipment and any equipment alarms.
4. Ask about any suspected complications or possible adverse reactions associated with the drug.

Paramedics who are transporting a patient who is receiving an unfamiliar drug(s) should have ready access to an infusion drip chart or electronic drug dose information source (Figure 21) (Box 7).

MANAGING TRANSPORT VENTILATORS

Transitioning a patient from a hospital ventilator to a transport ventilator (and vice versa) is often a complicated procedure. It also can be a source of anxiety for the patient and the paramedic crew (Figure 22). Although there are many ventilator devices used in both in-hospital and prehospital care, guidelines for transition between the devices should be followed.[6] These include:

1. Prepare all necessary equipment and supplies.
2. Check that all equipment is functioning properly. Ensure sufficient oxygen is available for transport by calculating flow rate, and volume consumption versus the amount of available oxygen.
3. Ensure emergency airway equipment is readily available.

FIGURE 21 Drug infusion during critical care transport.

FIGURE 22 Transferring a patient with a transport ventilator.

4. Assemble all equipment near the head of the stretcher.
5. Disconnect the patient from the mechanical ventilator and put the ventilator on standby.
6. During transition, ensure mechanical ventilation continues with 100% oxygen. The rate and depth of mechanical ventilation should closely simulate the rate and depth of what was provided by the ventilator.
7. Transition the patient to the transport ventilator and set the ventilation parameters as prescribed.
8. Closely observe the patent for tolerance of the change in mode of ventilation.

Ventilator Alarms

Ventilator alarms are set to warn of mechanical or physiologic problems. Therefore, continuous monitoring of the patient and alarm parameters is important. During transport, ventilator alarms may be difficult to hear. The alarms should be set to maximum volume, and the ventilator should be positioned so that flashing warning lights are visible. Table 2 provides guidelines for troubleshooting common ventilator alarms.

BOX 7 IV Drugs Used in Critical Care*

Abciximab
Alteplase
Aminophylline
Amiodarone
Argatroban
Atracurium
Bivalirudin
Cisatracurium
Conivaptan
Dexmedetomidine
Diltiazem
Dobutamine
Dopamine
Drotrecogin alfa
Epinephrine
Eptifibatide
Esmolol
Fenoldopam
Haloperidol
Heparin
Ibutilide
Immune globulin
Inamrinone
Infliximab
Insulin
Isoproterenol
Labetalol
Lepirudin
Lidocaine
Lorazepam
Magnesium sulfate
Midazolam
Milrinone
Nesiritide
Nicardipine
Nitroglycerin
Nitroprusside
Norepinephrine
Octreotide
Pantoprazole
Phenylephrine
Potassium chloride
Procainamide
Propofol
Reteplase
Tenecteplase
Tirofiban HCL
Vasopressin

*All infusions should be verified through medical direction or written protocol.

TABLE 2 Troubleshooting Ventilator Alarms

1. Initial assessment:
   Airway: Is the endotracheal tube (ETT) in correct position? Check ETT insertion depth, check end tidal CO_2, check breath sounds.
   Breathing: Check breath sounds, look for chest excursion, check pulse oximetry, check patient color.
   Circulation: Check the pulse, electrocardiogram (ECG), and blood pressure.
2. Remove patient from the ventilator and manually use a resuscitation bag if any compromise is found.
   Alarm
   Cause
   Management
   Apnea
   Insufficient spontaneous breathing by patient in CPAP or pressure-support mode
3. Switch ventilator mode to one that provides set rate
   High airway pressure
   ETT obstruction: sputum, kink, biting
   Decreased compliance or increased resistance
   Circumferential burns
   Bronchospasm, lung collapse, pneumothorax, endobronchial intubation, worsening of lung process
   Anxiety/fear/pain/fighting of ventilator
   Suction airway
4. Treat cause of resistance
   Adjust mode or settings
   Rule out hypoxia before treating agitation
   CXR analysis
   Change ventilator mode to one that is better tolerated or provides sedation/analgesia
   Low airway pressure
   Ventilator disconnect
   Leak in ventilator system
   Cuff leak
   Inadvertent extubation
   Ensure that all connections are intact and tight
   Troubleshoot ETT cuff
   Bag-valve-mask if ETT was dislodged
   Oxygen pressure low
   Oxygen cylinder is empty
   Closed cylinder valve
   Unit not connected to wall terminal
   Aircraft/ambulance oxygen flow in off position
   Check wall and cylinder connections
   Bag-mask-ventilate until resolved

From ASTNA: *ASTNA patient transport: principles and practice,* ed 4, St Louis, 2009, Mosby.

EXTRACORPOREAL MEMBRANE OXYGENATION (ECMO) SUPPORT

Extracorporeal Membrane Oxygenation is temporary support of a patient's heart and lung function by partial cardiopulmonary bypass (up to 75% of cardiac output). It is often used for patients who have reversible cardiopulmonary failure from pulmonary, cardiac, or other disease, and is often used in infants. With ECMO, blood is drained from the patient to an external pump. The pump pushes the blood through a membrane gas exchanger (for oxygenation and CO_2 removal) and a warmer (Figure 23). The blood is then returned to the patient's circulation. ECMO requires anticoagulation of the patient usually with unfractionated ***heparin***, guided by frequent measurements of activated clotting time (ACT). Various devices monitor the patient,

and the pressures, flow, and temperature of the ECMO blood and gas circuits. ECMO can be either veno-arterial or veno-venous[7]:

- *Veno-arterial (VA)-ECMO,* can be central, in which blood is drained from the right atrium (via a right internal jugular venous catheter) and is returned to the thoracic aorta (via a right carotid arterial catheter). It may also be peripheral, in which the blood is often drained from a femoral artery and returned via a femoral vein approach into the inferior vena cava. VA-ECMO provides cardiac as well as pulmonary support.
- *Veno-venous (VV)-ECM* can also be central or peripheral. In central VV-ECMO blood is drained from right atrium (via side holes of a double lumen catheter) and returned to the right atrium through the end hole of the catheter, which is directed toward the tricuspid valve. Peripheral VV-ECMO may involve the femoral artery to femoral vein approach; femoral vein to femoral vein; or femoral vein to internal jugular vein if circulation is intact. VV-ECMO requires good cardiac function and avoids cannulation of the carotid artery. With improved ECMO technology, the less invasive approaches are most commonly used when possible.

The duration of ECMO treatment is usually limited to 7 to 10 days for neonatal respiratory diseases. Longer treatment may be needed for newborns with diaphragmatic hernia and cardiac disease, and in older children or adults. Complications of ECMO treatment include severe bleeding (gastrointestinal hemorrhage, intracranial bleeds), thromboembolism, air embolism, limb ischemia, acute renal failure, and oxygenator failure.[8]

Transport Considerations

Interfacility transport of ECMO patients is uncommon. This is because most institutions that initiate ECMO treatment are well-qualified to continue the patient's care. However, EMS transports do occur for reasons such as suboptimal cardiothoracic physician staffing, centers that are not capable of initiating ventricular assist device (VAD) therapies in the patient (described in Chapter 22), and institutions that do not have cardiac transplant capabilities. ECMO patients are extremely ill. Because of this and the complexity of the ECMO apparatus, most interfacility transports are provided by medical teams to ensure safe transport. Additional staff may include a cardiothoracic surgeon, a clinical perfusionist, and an anesthesiologist or nurse anesthetist. Often the EMS crew will only assist with safely moving the patient and equipment.

NOTE
It is critical that all devices placed in the ambulance be strapped in place to prevent inadvertent movement during transport. Additionally, all team members must have the ability to sit and be seat-belted while the vehicle is in motion.

FIGURE 23 Extracorporeal membrane oxygenation. (Hockenberry MJ, Wilson D: *Wong's nursing care of infants and children*, ed 9, St. Louis, 2011, Mosby.)

As noted earlier, these patients are extremely ill. They often require multiple vasopressors and blood products to maintain adequate hemodynamics.[9] If possible, continuous IV infusions that are nonessential or that can be given IV push should be discontinued or switched to smaller IV pumps to preserve space in the ambulance. All IV lines and insertion sites should be labeled and secured. (Surgical and arterial sites should be evaluated often for bleeding and after each move.)These patients often require continuous monitoring of arterial and central venous pressures, end-tidal CO_2, ECG, blood pressure, and core temperature. Once completely prepared for movement, the patient should be moved to and from the EMS stretcher with as much assistance as possible.

Abandoned call, 78
Abandonment, 100
  definition of, 88
  elder, 1412, 1420, 1422
Abbreviations, 131-132, 136t
Abciximab (ReoPro), 316b, 1575
Abdomen, 1221, 1221f-1222f
  auscultation of, 544, 893
  congenital anomalies of, 1315-1316
  examination of, 542-546, 679
  inspection of, 542-544, 544f, 892-893
  of pediatric patient, 1341
  percussion and palpation of, 545-546, 545f, 893
  quadrants of, 146-147, 150f, 543f, 544b, 1221f
Abdominal aorta, 139, 188, 694f
Abdominal aortic aneurysms, 570, 693-696, 694b
  in geriatric patient, 1398, 1398b
  pain from, 890t
Abdominal cavity, 147, 150f
Abdominal emergencies
  management of, 893, 893f
  specific, 894-904, 894b
Abdominal pain
  acute, 887-893, 887f
    causes of, 890t
    history of, 889
    location and type of, 889-891, 892f
    management of, 893, 893f
    physical examination of, 892-893
    signs and symptoms of, 891-892, 891b, 891t
    vital signs for, 892
  age-related variations in, 904
  in gynecological emergencies, 937, 937t
Abdominal reflexes, upper and lower, 553, 553t
Abdominal surgery, 889b
Abdominal trauma, 1220-1229, 1220f
  assessment of, 1226-1227
  blunt, 1222, 1223f
  in child abuse, 1378, 1424
  compression, 1088
  deceleration, 1087, 1087f
  in geriatric patient, 1227b, 1410
  management of, 1227-1228, 1228f
  mechanisms of, 1221-1223
  organ injuries in, 1223-1226, 1224f
  in pediatric patient, 1227b, 1372
  penetrating, 1097, 1119, 1223
  prehospital care for, 1222b
  prevention of, 1221b
  signs of, 1223b
  vascular injuries in, 1226
Abdominopelvic cavity, 147, 150f
Abducens nerve, 179f, 180t, 551, 777t
Abduction, 167t, 169f, 964f
Aberration, 570, 588b
ABO blood groups, 245, 246f
Abortion(s)
  classification of, 1291b
  number of, 1280
  spontaneous, 1275, 1291
Abrasions, 1100, 1106, 1106f
  in child abuse, 1377f
  corneal, 720, 722-723, 1146, 1154, 1156f
  road rash-type, 1089, 1089f
Abruptio placentae, 1274, 1292-1293, 1292t
Abscess
  Bartholin's, 928, 933
  brain, 764, 790
  dental, 720, 733-734
Abscess *(Continued)*
  peritonsillar, 721, 736
  rectal, 887, 901b
Absence seizures, 764, 786
Absolute refractory period, 570, 586, 586f
Absorption
  drug, 276, 283-284, 288f
    in geriatric patient, 296
    in pediatric patient, 295
    route of administration and, 284-286, 284t
  poisoning by, 1002-1004
    management of, 1003-1004
    signs and symptoms of, 1002-1003, 1003b
Abuse and neglect, 1415-1428, 1416f. *See also* Drug abuse.
  battering in, 1416-1420
  characteristics of persons in relationships with, 1418-1419
  child, 1333, 1375-1378, 1376b, 1421-1425
    characteristics of abusers, 1422-1423, 1423b
    characteristics of victims, 1423, 1423b
    deaths from, 1424-1425
    physical examination for, 1423-1424
  economic, 1415-1416
  elder, 1388, 1411, 1415, 1420-1421
    signs and symptoms of, 1412b, 1422b
    types of, 1420-1421, 1421f
  emotional, 1412, 1415-1416, 1420, 1422
  physical, 1412, 1415-1416, 1420, 1421f, 1422
  sexual, 1412, 1415-1416, 1420, 1422, 1425-1427
  types of, 1416
Abusers
  child, 1375, 1422-1423, 1423b
  elder, 1422b
  lies told by, 1419b
Acarbose (Precose), 812t
Accelerated junctional rhythm, 570, 633, 634f
Acceleration, 1076, 1082
Acceptance, 45
Accessory muscles, 384, 395, 396f
Accessory pathway syndrome, 607-608
Accidental Death and Disability: The Neglected Disease of Modern Society, 4, 4b
Accountability
  legal, 93-96, 96b, 111
  moral, 111-112
  paramedic, 116
  professional, 111
ACE. *See* Angiotensin-converting enzyme.
Acetabulum, 139, 162
Acetaminophen, 986t, 1014-1015, 1015b
Acetate, 800, 808
Acetonemia, 989
Acetylcholine, 299, 299b, 301t
  actions of, 301, 301t, 768t
  definition of, 276
  emotions and, 308, 308b, 309f
N-Acetylcysteine, 1015
Achilles reflex, 553t, 554, 555f
Achilles tendon, 1230
Achilles tendon rupture, 1230, 1248b
Acid(s), 225-226, 226f
  definition of, 211
  ingestion of, 986-987, 986b
Acid-base balance, 225-232
  buffer systems in, 226-227, 227f
  definition of, 211
  disturbances in, 227-230
    acidotic, 227-230, 228f-229f
    alkalotic, 230-232, 230f-231f
    mixed, 232
    primary points for, 232
  laboratory studies of, 232b
Acid-base balance *(Continued)*
  measurements of, 227b
  pH in, 225-226, 226b, 226f
Acidosis, 227-230
  definition of, 211, 227
  in diabetes, 811
  diabetic ketoacidosis, 229-230, 800, 813-814
    causes of, 813b
    dehydration in, 1367f
    differential diagnosis of, 818t
  lactic, 213, 228-229, 259
  measurements of, 227t
  metabolic, 228-230, 229f
    methanol poisoning and, 988
Acini, 804-805
Acoustic nerve, 179f, 180t, 208, 208f
  assessment of, 551, 777t
  injuries to, 1163
Acoustic neuroma, 764, 794
Acquired immune deficiencies, 247-248, 248b
Acquired immunity, 245, 824, 828, 828f, 828t
Acquired immunodeficiency syndrome, 248b, 846b. *See also* Human immunodeficiency virus.
Acrocyanosis, 1307, 1319
Actidose (activated charcoal), 1575-1576
Actin, 167
Action plan, 1567-1569, 1569f
Action potential, 583, 767, 769f
  definition of, 139, 155, 764
  propagation of, 583-586, 585f
Activated charcoal (Aqua, Actidose, Liqui-Char), 985, 1575-1576
  for acetaminophen overdose, 1015
  administration of, 351
  for beta blocker toxicity, 1013
  for cholinergic overdose, 1020
  for digoxin toxicity, 1013
  dosages for, 985b
  for drug overdose, 1005
  for hydrocarbon ingestion, 987
  indications and contraindications for, 985b
  for iron poisoning, 989
  for isopropanol poisoning, 989
  for lithium overdose, 1012
  for methanol poisoning, 988
  for monoamine oxidase inhibitor toxicity, 1013
  for plant poisoning, 991
  for salicylate overdose, 1014
  for toxic syndromes, 1020t
Active immunity, 827-828, 828b, 828f
Active labor, 1293b, 1294
Active listening, 20b, 481b
Active transport, 211, 218
Active tubular secretion, 289
Activities of daily living, instrumental, 558
Actos (pioglitazone), 812t
Acute arterial occlusion, 570, 696-697, 697f-698f
Acute chest syndrome, 942, 956b
Acute coronary syndrome (ACS), 679-699. *See also* Myocardial infarction.
